

# ecalj manual

<https://github.com/tkotani/ecalj>

November 9, 2015

## Abstract

**ecalj** is an all-electron full-potential electronic-structure calculation package, especially for GW/QSGW calculations, in addition to its unique one-body problem solver which uses both augmented plane wave (APW) and the Muffin-tin orbital (MTO) simultaneously. Available freely from github.

This is based on the formulation in Refs. [1] and [2] (See Kotani2114QSGWinPMT.pdf and KotaniKinoAkai2015FormulationPMT.pdf at ecalj/Document/Manual/) on top of developments [3]. By **ecalj**, we can do QSGW and related calculations based on the  $\text{PMT}=\text{LAPW}+\text{LMTO}$  method. To get minimum usage for ecalj, read up to the Section.5 or Sec.7. (We can generate model Hamiltonian through Wannier functions(ecalj/MATERIALS/CuMLWF, and so on, but not documented well yet...)

Be careful. This document still contain many bugs... Let me know bugs in this manual (try to fix things step by step). We need your help on this manual.

---

## Requirement

To support of our ecalj activity, we need your acknowledgment to **ecalj** in your publications in the manner shown in ecalj/README.md;

<https://github.com/tkotani/ecalj/#we-need-acknowledgment-as> such as:

[1] ecalj package at <https://github.com/tkotani/ecalj/>.

Its one-body part is developed based on Ref.[2].

[2] LMsuit package at <http://www.lmsuite.org/>.

Its GW part is adopted mainly from Ref.[1].

(as in the same manner of usual papers).

## Contributions

Main contributors to the ecalj package are (only a list of people who directly related to the code developments):

T.Kotani, Hiori Kino, Mark van Schilfgaarde, Sergey Faleev, Takashi Miyake, Seungwoo Jang, Manabu Usuda. They also contribute to this documents.

## Relation with LM suit at <http://www.lmsuite.org/>:

There is a full potential LMTO package (with a slightly different implementation of PMT) contained in **lmsuit**. In the package, there is the driver to use a modified version of the GW code in **ecalj** (GW part in **ecalj** is occasionally adopted in **lmsuit**). The FP-LMTO in **lmsuit** and **ecalj** have some similarities (for input files and outputs). Thus some part of its document in the web site is still applicable even to the ecalj package.

## History

T.Kotani learned the LMTO-ASA-GW code by F.Aryasetiawan, which is on top of the Stuttgart's LMTO-ASA, mainly by van Schilfgaarde under O. Jepsen and O. K. Andersen

<http://www2.fkf.mpg.de/andersen/LMTODOC/LMTODOC.html>. A FP-LMTO package is originally given by M.Methfessel, Mark van Schilfgaarde and their collaborators. T.Kotani developed an all-electron full-potential GW method on top of the FP-LMTO during his subbatical at 1999-2000 at the lab of M.Schilfgaarde. Then the QSGW method has developed with the help of S.Faleev and M.Schilfgaarde, first published in 2004. Then T.Kotani was adding new functionality such as spin fluctuation, impact ionization. In year 2008, T.Kotani started the PMT=LMTO+LAPW method to remove problem of the FP-LMTO. After T.Kotani moved to Tottori-u at 2009, he spends time for the improvement of PMT method. T.Kotani and H.Kino showed that the PMT method can describe even the diatomic molecules efficiently and accurately. It turns out very limited number of APWs can remove such problems. Then T.Kotani have developed PMT-QSGW method. It is now stable, easy, and reliable rather than the previous version of QSGW on top of FP-LMTO.

# 1 Introduction

The **ecalj** is an first-principles electronic-structure calculations package with some unique features. With **ecalj**, we can do not only standard calculations (LDA/GGA/LDA+U, relaxation of atomic positions), but also the quasiparticle self-consistent GW calculations(QSGW), linear responses (charge and spin), Wannier functions (and U of them).

This is base on an unique one-body problem solver, the PMT method (=the Linearized APW+MTO method) [1]. Thus we identify the QSGW method implemented in **ecalj** as the PMT-QSGW method. Introduction to the PMT-QSGW is given in Sec.1.1. Today “QSGW” is accepted as a standard procedure in the electronic structure calculations [4].

First, see README.md shown at <https://github.com/tkotani/ecalj#ecalj-> (or `ecalj/README.md` in the package). Free to download **ecalj** package from it, and use it. The QSGW code is version controlled by git.

The **ecalj** is related to a FP-LMTO package `lmv7` seen at <http://titus.phy.qub.ac.uk/packages/LMTO/fp.html>. The `lmv7` and `ecalj` are branched off at year 2009. After branched, main contributions are due to T.Kotani and Hiori Kino (NIMS) until now. We added new features: simple install and test; all codes are in `f90` (no C compiler); new methods, especially PMT-QSGW; MPI parallelization for QSGW; simple usage with automatic setting of default files by python ver2; a small tool to convert VASP POSCAR to `ecalj`, and so on. PMT-QSGW shows more stable convergence than the previous version, FP-LMTO-GW <sup>1</sup>.

---

**ecalj** package mainly consists of two parts. One is one-body part(PMT part) (in `ecalj/lm7K/`), the other is many-body part(GW part) (in `ecalj/fpgw/`).

**One-body part (PMT part)**, based on [1]

We can perform standard calculations such as LDA,GGA,LDA+U, atomic position relaxation, and so on. In addition, the PMT part has an interface to perform GW (and QSGW) calculation: the one-body part can include a given non-local exchange-correlation potential stored in a file `sigm.*`. <sup>2</sup>. The QSGW calculation is performed by a script `gwsc`, which has an iteration loop calling the one-body program (`lmf`) and many-body part (GW part) alternatively. The many-body part generate the file `sigm.*`. See Fig.6 and around.

**Many-body part (GW part)**, based on [2]

As the inputs for the GW calculation, we have to supply the eigenfunctions and the eigenvalues from the one-body part to the GW part. The eigenfunctions re-expanded by the two types of basis functions, the atomic-like argumentation functions in the muffin-tin(MT) spheres, and the plane-waves in the interstitial region, say, the interstitial plane-wave (IPW) hereafter. IPW is defined as the usual plane waves in the interstitial region, but zero within MTs’. The IPWs + ”atomic like functions within MTs” make “a basis set to expand eigenfuncitons”. See Eq.(17) of [2].

We need another basis set to expand “product of eigenfuncions”. That is, the mixed product bases (MPB)

[5, 6], which consists of the two kinds of bases (caution: do not mixed up with the basis set for eigenfuncitons); (i)the local atom-centered functions confined to MT spheres, so-called the product basis; (ii) IPW. The product-basis are calculated from products of solutions to the Schrödinger equation within the MT sphere. The Coulomb matrix  $v$ , the dynamically screened Coulomb interaction  $W$ , and so on, are expanded in the MPB. It can virtually span all the space made of product of eigenfunctions (but, in practical calculations, we need to use a small

---

<sup>1</sup>In cases to treat magnetic systems which have intrinsic magnetic fluctuations, we may need to be careful about initial condition or mixing procedure to get convergence. In cases, we need to start from LDA+U results as initial condition from which we start QSGW. Let me know about such trouble.

<sup>2</sup>In the case of using `sigm.*`, total energy shown in the console output (also in `save.*`) are just the indicator, not the meaningful total energy

size of the bases to reduce computational time). We include full energy-dependence of  $W(\omega)$ . See Sec.3 of [2].

Recently T.Kotani includes the Wannier function generator, which was originally developed by T.Miyake and H.Kino on top of previous version of GW part. Thus the Wannier functions (including effective interactions) can be generated in the PMT-QSGW. (U parameters in the full-screening and cRPA).

## 1.1 Uniqueness of the ecalj package.

We will explain two unique points of **ecalj**.

### PMT:

Central part in an electronic structure packages is one-body problem solver. It means how to calculate eigenvalues/eigenfunctions for a given one-body potential. Inversely, we have to generate new one-body potential for given eigenfunctions/eigenvalues based on the density functional theory (DFT) in the LDA or GGA (In the followings, LDA means both of LDA and GGA). Then we can make the electron density self-consistent by iterations until converged, and obtain total energy of ground states. Then we can calculate atomic forces by perturbation. Based on such an one-body problem solver, we can implement kinds of methods; e.g, dielectric function, magnetic susceptibility, transport and so on. Furthermore, we can implement higher-level approximations such as the QSGW method explained below. An one-body problem solver (in linear methods) are characterized by

- (i) linear combinations of what basis set to represent eigenfunctions;
- (ii) how to represent electron density and one-body potential.

In **ecalj**, we use the PMT method [1, 7] as the one-body problem solver. The PMT method is a new all-electron full potential method. It uses not only the augmented plane waves (APW) but also the muffin-tin orbitals (MTO) together, in addition to the local orbital (lo's), to represent the eigenfunctions (no other methods use two kinds of augmented waves together). Thus eigenfunctions are expanded in the linear combinations of the APWs, MTOs, and the lo's. The formulation is clarified in Ref.[1]. Then the electron density and the one-body potential are given in the "3-components representation". That is, the electron density (one-body potential) is divided into three components,

"smooth part + onsite muffin-tin (MT) part - counter part".

Here the counter part is in order to remove smooth part within MTs. This formalism (Soler-Williams formalism [8, 9]) is also used in the projected augmented wave (PAW) method such as VASP.

We now usually use highly localized MTOs together with APWs of low energy cutoff ( $3 \sim 4$  Ry).<sup>3</sup> I think this is promising not only for efficient DFT/QSGW scheme, but also for kinds of applications in future.

### QSGW:

In **ecalj**, we can perform the GW calculation. The usual GW approximation is so-called "one-shot GW" starting from LDA. It usually only calculates differences between the quasi-particle energies (QPEs) and the LDA eigenvalues by a perturbation (only diagonal part of self energy for the LDA eigenfunctions). Its ability is limited; it may fail when its starting point (eigenfunctions and eigenvalues supplied by LDA) is problematic. This is the reason why we originally develop the QSGW method. The QSGW now becomes popular and taken as a possible candidate to go beyond current limitation of such GW and LDA/GGA [4]. In principle, results given by QSGW do not depend on LDA anymore; the LDA are only used to prepare initial condition for self-consistency iteration cycle of the QSGW calculation<sup>4</sup>.

Usually the QPEs obtained by QSGW reproduce experiments better than LDA. For example, the band gap by GGA for GaAs is about 0.5 eV in contrast to the experimental value of 1.69 eV<sup>5</sup>. On the other hand, the QSGW predicts about 1.8~1.9eV, a few tenth of eV larger

<sup>3</sup>current implementation have not yet efficiently use this locality; this must allow us to speed up one-body problem solver.

<sup>4</sup>Exactly speaking, we use LDA idea for efficient implementation of QSGW; thus obtained results are slightly dependent on the choice of LDA or GGA

<sup>5</sup>We undo electron-phonon effect (0.06eV) and spin-orbit effect (0.11eV) from the true the experimental value

than experiment (for practical use, we sometimes use “hybrid functional between QSGW and LDA” so as to obtain smaller band gap). Even in the case of NiO and so on, the QSGW gives reasonable results (there is a tendency to give a little larger band gaps than experiments). This is in contrast to the case of the one-shot GW applied to NiO, where we can not have good agreement with experiments because the starting points in LDA is problematic.

The **ecalj** have other functions. LDA+U, atomic forces and relaxation (in GGA/LDA), core level spectroscopy and so on. In addition, we can calculate dielectric functions and magnetic responses from QPEs and the quasiparticle eigenfunctions given by LDA/QSGW. But total energy in QSGW is still in research (shown total energies in QSGW calculations are dummy now).

The QSGW calculations are very time-consuming; roughly speaking, it takes 10 or more times expensive than usual one-shot GW (although we can reduce computational time by choosing computational conditions). Thus the size of systems which we can treat is limited to ten atom in a cell or something, say, with a node of 16 cores; computation may require a week or so to have reasonable convergence. (heavy atoms require longer computational efforts, light atoms faster; non-magnetic systems are easier. We still have much room to accelerate the method, but not have done yet so much. Minimum MPI parallelization is implemented). The computational effort is  $\propto N^4$  in the most time-consuming part of QSGW.

### 1.1.1 What do we expect for QSGW?

Let us recall hybrid functionals such as B3LYP, and LDA+U. In hybrid functional methods, we use  $V_{xc} = (1-\alpha)*LDA + \alpha*(\text{Fock exchange like term})$ , where  $\alpha$  is taken to be  $\sim 0.25$  usually<sup>6</sup>. The  $\alpha$  can be dependent on materials; for metals  $\alpha$  should be almost zero. For larger band gap insulator,  $\alpha$  becomes larger.<sup>7</sup> Despite of success of the functional, its ability is limited. For example, it is known that a hybrid functionals fail to describe metals such as bcc Fe. On the other hand, we have LDA+U method which succeeded to describe materials including localized electrons. However, it contains kinds of ambiguity and U is chosen by hand. The important part of the hybrid functional methods and LDA+U is the non-local potential. It is missing in the DFT. As we discussed above, they give some success but not satisfactory. We somehow need to have a method to determine high-quality non-local potential (a substitution of the exchange-correlation potential in LDA). It is the QSGW method.

Note two important aspects of non-local potential (missing character in the local potential used in DFT). One is the onsite non-locality; it is also taken into account by LDA+U model. However, note that relative shift of O(2p) band with respect to the center of 3d band is not in LDA+U. The other is the off-site non-locality (mainly between nearest neighbors), which may relate to LUMO-HOMO gap. A non-local potential can behave a projector which push down only the HOMO states (valence band) to lower energy. This can be in the hybrid functional but not in LDA+U.

In the QSGW, we determine such a non-local potential with the calculation of the GW method, in a self-consistent manner (we repeat GW calculations until converged). We can expect QSGW much more than hybrid methods/LDA+U. Roughly speaking, because the QSGW automatically determine U of LDA+U, or alpha of the hybrid functionals. More accurately speaking, we determine not only  $G_0$  but also  $W$  (the screened Coulomb interaction) self-consistently. Here  $W$  corresponds to U and alpha. Thus QSGW gives reasonable results even if it is applied to metals such as Fe. For systems with metallic screening, it gives small non-locality (results are close to those of LDA). For systems with large band gap, QSGW gives large enough non-locality (like  $0.25*(\text{Fock exchange})$ ).

Since we now need to treat complex systems, e.g, metal on insulator, it is very essential to treat kinds of materials on a same footing.

The main purpose of QSGW is to determine an one-particle effective Hamiltonian  $H^0$ <sup>8</sup>, which describes the quasiparticle picture (or independent-particle picture) for the sys-

---

1.52 eV.

<sup>6</sup>exactly speaking, we have range cutoff for Fock exchange term in the HSE functional in addition

<sup>7</sup>If you use  $\alpha = 1$  (Hartree-Fock limit), the band gap of Si becomes 20eV or something.

<sup>8</sup>people often pronounce this H-naught

tem we calculate. In other words, QSGW divides the full many-body Hamiltonian  $H$  into  $H = H^0 + (H - H^0)$ . The screened Coulomb interaction  $W$  is determined self-consistently in the QSGW iteration cycle.

In comparison with LDA, we see differences;

- Band gap. QSGW tends to give slightly larger than experiments. It looks systematic.
  - Band width. Usually, sp bands are enlarged (except very low density case such as Na). This is the case for homogeneous electron gas. As for localized bands like 3d electrons, they can be narrowed.
  - Relative position of bands. e.g. O(2p) v.s. Ni(3d). More localized bands tends to get more deeper. Exchange splitting between up and down (like LDA+U) get larger. In cases such as NiO, magnetic moment become larger; closer to experimental values.
  - Hybridization of 3d bands with others. QSGW tends to make eigenfunctions localized.
- However, reality is complexed, and not so simple in cases.

## 1.2 Rule in this manual

- **This font** is for executable file(program) or shell scripts.
- **echo 3|hbasfp0** means doing **hbasfp0** with the argument '3' supplied as the standard input (read(\*,\*) in fortran).
- **This font** is for files, directories, contents of files, or variables used in codes.
- **ctrl.si,rst.si** and so on mean the case of Si. You may need to replace the extension **si** for your case. (this extension is given by user. Lower case, number, and underscore [a-z0-9\_] are allowed.) In the followings, **ctrl.\*** means a file wish such an extension.
- There are files named **foobarU** and **foobarD**, which are for up spin (isp=1) and for down spin (isp=2), respectively; for example, **SEXU** and **SEXD**. We sometimes use **foobarU** to denote **foobarU** and **foobarD** together.
- **k** vector in the Brillouin zone is called as **q** or **k**.

## 1.3 What can we do with the ecalj package?

At Feb.2015, what we can do is as follow. We have limited parallelization. (e.g. k point parallel).

- LDA/GGA LDA+U, calculations, atomic forces and relaxation. Spin-orbit is included only for co-linear spin-density cases.
- Quasi-particle(QP) energy in the 1st-iteration from LDA. (one-shot *GW*)  
Make band plot for LDA and the QP energies.
- Spectrum function of the self-energy  $\Sigma$ . Life time (imaginary part) of QPs.
- Dielectric function, and its inverse. (including local-field effect or not).
- QP self-consistent *GW*(QSGW)
- magnetic susceptibility.
- Wannier function. (not only one-body part, but also effective interaction  $W$  and cRPA)

## 2 Install

Install and minimum tests are easy; even in a note PC, e.g., we can use gfortran in Ubuntu 14.04 on e.g., Thinkpad T420s for a test purpose. For productive runs, we may need multi-cores. Current implementation for parallelization by MPI is limited (not so much especially for the dielectric function part yet). Thus, probably, it may be not so efficient to use too many cores.

Follow the instruction of `ecalj/README.md`.

or we can see the same one at <https://github.com/tkotani/ecalj/#install-and-test>. We have a command `ecalj/InstallAll.ifort` and so on. This command installs `ecalj` and run a series of install tests automatically.

### 2.1 Binaries and Scripts

Binary and Scripts contained in `ecalj` are

- `ctrlgenM1.py`  
Generate default input file `ctrl.*` from the structure file `ctrls.*`. The latter file only contains information of crystal structure.
- `lmfa`  
Spherical atom calculation as initial condition, and core charge
- `lmchk`  
Check atomic positions, crystal symmetry, and computational conditions.
- `lmf` and `lmf-MPIK` LDA/GGA, LDA+U calculations. (or we can use `Vxc` in QSGW instead). We mainly use `lmf-MPI` (k-parallel version) instead of `lmf`.
- PROCAR mode of `lmf`: Fat band mode.  
`mpirun -np 4 lmf-MPIK --mkprocar --band:fn=sym1 mgo` gives PROCAR  
(Try an example `/ecalj/MATERIALS/MgO-PROCAR/`. Run `./job` at the directory).
- `gwsc`  
QSGW calculation
- `job_band`, `job_fermisurface`, `job_tdos`, `job_pdos`  
band, fermi surface, tdos, pdos plot.
- `epsPP_lmfh`  
Dielectric function without local field correction (LFC).
- `eps_lmfh`  
Dielectric function with LFC
- `epsPP_lmfh_chipm`  
Non-interacting transverse spin polarization.
- `gw_lmfh`  
One-shot GW calculation. This also show life-time of QPs (`QPU_lmf`). (we need make it parallelized...)
- `genMLWF`  
Wannier functions and matrix elements of  $W$  on it. A implementation of cRPA included.
- `dqpu`  
A small python script to compare `QPU.*` files (eigenvalues are compared) numerically. (Seungwoo say it cause “index error”; Need to fix `dqpu` if something strange).

### 2.2 tests

`Install.ifort` run tests at `ecalj/TestInstall`.

In the following, `si:gw_lmfh` means `>make si_gw_lmfh` at `ecalj/TestInstall/`; this test is performed with the Makefile at the directory.

si:gw_lmfh/	Results: QPU
si:gWSC/	: QPU,log.si
gas:gWSC/	: QPU,log.gas
nio:gWSC/	: QPU,log.nio
fe_epsPP_lmfh_chipm:	: ChiPM*
gas:eps_lmfh/	: EPS*
gas:epsPP_lmfh/	: EPS*

(These are just samples; not for practical calculations)

## 2.3 Directory structure

### 3 Theory (note)

Except the technical details, we need to know minimum for these theories.

- DFT in LDA/GGA.
- GW
- QSGW

There are literatures as for GW. A recent one is Ref.[4]. In addition, it is better to know the basics of the PMT method (LAPW+LMTO method) [1]. Here is a small note for *GW*.

#### Green function

The Green's function  $G(\mathbf{r}, \mathbf{r}', \omega)$  is the central quantity in the GW calculation. In the one-particle theory (mean-field theory/non-interacting case), the Schrödinger eq. is

$$(i\frac{\partial}{\partial t} - H_0)\psi(\mathbf{r}, t) = 0 \quad (1)$$

Here  $H_0$  is the one-particle Hamiltonian which contains electrostatic potential plus exchange-correlation potential  $V_{xc}$  (here we don't care how it is given. This should be static but can be non-local as Fock term). When we have (unknown) source term  $J(\mathbf{r}, t)$  instead of 0 in the right hand side of Eq. (1), we can calculate  $\psi(\mathbf{r}, t)$  by multiplying inversion of the operator  $(i\frac{\partial}{\partial t} - H_0)$ . This is the (non-interacting) Green function  $G(\mathbf{r}, \mathbf{r}', \omega)$  defined as

$$(i\frac{\partial}{\partial t} - H_0)G = \delta(t - t')\delta(\mathbf{r} - \mathbf{r}'). \quad (2)$$

As this shows,  $G$  is the inverse matrix of the operator  $(i\frac{\partial}{\partial t} - H_0)$ , (we pay attention to the boundary condition, especially for time-direction: retarded, advanced or time-ordered). Thus we can write  $G = 1/(i\frac{\partial}{\partial t} - H_0) = 1/(\omega - H_0)$ . In other words, the Green function  $G$  is the integration kernel in order to convert a differential equation Eq. (2) to an integral equation. This is the same as the case of Poisson equation (Laplacian) for the electrostatic problem; then  $1/|\mathbf{r} - \mathbf{r}'|$  is the Green function for the conversion (then we calculate electro static field  $\phi(\mathbf{r})$  for give source term  $\rho(\mathbf{r})$ ).

In the case of electro static problem, we have two ways to solve the problem. One is the direct method to solve differential equation, the other is using such integration kernel. They are equivalent, but the latter is easy to handle and suitable for numerical calculations (under the assumption of "superposition law", that is, linear response). Although  $G(\mathbf{r}, \mathbf{r}', t - t')$  contains time variables (to describe wave propagation), essentials are the same.

#### Green function: many body case

$G(\mathbf{r}, \mathbf{r}', \omega)$  is the quantity which is well defined even in the many-body perturbation theory. It is defined as the expectation value as  $\langle 0|\hat{\psi}(\mathbf{r}t)\hat{\psi}^\dagger(\mathbf{r}'t')|0\rangle$  (this is not accurate. See literatures..). Here we use the second-quantized field-operator  $\hat{\psi}$ . This definition of  $G$  is a natural extension of the one-particle case.

However, there are differences in the  $G$  of one-particle case and many-body case. In the one-particle case, we have no interaction between electrons. Thus an electron added to the ground state (which is by filling electrons up the Fermi energy) is the eigenstate. An electron going on can not be an eigenstate, because of the correlation effect and exchange effect.

Let me explain the correlation effect. In contrast to this, one-particle state (=the quasi-particle(QP)) in the many-body theory can be not the eigenstate; it moves in the sea of other electrons and holes, which can be excited to other states, or an moving electron can move with polarized cloud of other electrons and holes. Its motion is affected by other electrons. It will lose energy gradually; the QP can have life time. This may be identified as the correlation effect.

Let me explain the exchange effect. This is due to the Fermi statistics. The electron, which you focus on, can not be distinguished from other electrons. (Thus mu-on can not feel this effect.  $G$  for mu-on in solids only contains pure correlation effect). From a point of view, this exchange effect is interpreted as a hopping effect, sudden jump from an electron to another electron (actually the Hartree-Fock theory gives zero effective mass at the Fermi energy for metallic systems).

We can include both of the effects in the GW calculation at the lowest order. Exactly speaking, these two effects are really mixed up. However, in GW (since GW is at the lowest order), these two are clearly separated.

The rigorous equation for  $G$  is

$$\left( i \frac{\partial}{\partial t} - H_0 + (\Sigma(\mathbf{r}, \mathbf{r}', t - t') - V_{xc}) \right) G = \delta(t - t') \delta(\mathbf{r} - \mathbf{r}'). \quad (3)$$

Only the difference is adding  $\Sigma(\mathbf{r}, \mathbf{r}', t - t') - V_{xc}$ . In other words, all unknown effects are pushed into this term. Many body effect are pushed into (downfolded or projected into) the self-energy (=dynamical one-particle potential)  $\Sigma(\mathbf{r}, \mathbf{r}', t - t')$ . We don't treat many-body quantities such as  $X(\mathbf{r}_1 t_1, \mathbf{r}_2 t_2, \mathbf{r}_3 t_3)$  directly in the GW calculations.

The GW method is how to give the  $\Sigma(\mathbf{r}, \mathbf{r}', t - t')$  in the lowest order. Because of the long-range property of the Coulomb interaction, we need to have a special technique (not a simple perturbation).  $\Sigma(\mathbf{r}, \mathbf{r}', t - t')$  is calculated as the product of  $G \times W$ , where  $G$  is (usually) just the non-interacting Green function given in Eq. (2).  $W$  is the dynamically screened Coulomb interaction calculated in RPA.

### QSGW

Note that Eq. (3) completely cancels the effect of  $V_{xc}(\mathbf{r}, \mathbf{r}')$  since it is included in  $H_0$ . Thus this division is not meaningful if we can solve a problem completely. However, what we can do is only the perturbation. Quantities for  $H_0$  is taken as the basic quantities. On it, we apply the perturbation. Equivalently we can have a division  $H = H_0 + (H - H_0)$ , where  $H$  is the many-body Hamiltonian.

In principle, we can start from any  $V_{xc}$ . However, as long as we use perturbation theory, we have to minimize the effect of  $\Sigma(\mathbf{r}, \mathbf{r}', t - t') - V_{xc}$ . The degree of freedom of the choice of  $V_{xc}$  is used to minimize it. This is the self-consistent perturbation theory idea for QSGW.

If  $\Sigma(\mathbf{r}, \mathbf{r}', t - t') - V_{xc}$  give small effect, we can use the concept of the QP (independent particle picture) as the basis to evaluate physical quantities.

We have to determine best (or optimum)  $V_{xc}$ . How to do it? An idea is that we should determine it so that the size of  $\Sigma(\mathbf{r}, \mathbf{r}', t - t') - V_{xc}$  should be smallest (how to measure the size?). Or, based on the Landau-Silin's theory, the QPs contained in  $G$  should be reproduced by  $H_0$ . In anyway, this ends up with the self-consistent perturbation theory. For trial  $V_{xc}$  (and electron density), we have  $H_0$ ; from  $H_0$  we can calculate  $\Sigma(\mathbf{r}, \mathbf{r}', t - t')$ . Then we have to determine new  $V_{xc}$  in a method. This is repeated until converged. No unique choice for the method. Thus we testes some possible ways and now we usually use a standard procedure as described in Ref. [2].

## 4 LDA/GGA calculations and Plots

Calculations are performed by following steps. These steps are detailed in the following sub-sections.

To identify a set of files used for a material we calculate, we use an extension to files. For example, files explained below are with extensions (only lower case allowed) of materials. For example, `ctrls.cu` and `ctrl.cu`. In this case `cu` is the extension. Any extension works. Other possible examples are `ctrls.lagao3`, `ctrl.wgantest1`, and so on.

1. Write crystal structure file `ctrls.*`, which contains crystal structure. It can be by hand, or convert it from POSCAR (in VASP). There is a tool to convert between POSCAR and `ctrls.*` (See `ecalj/StructureTool/README.txt` for the tool. we have `vasp2ctrl` and `ctrl2vasp`. Type them without arguments to see help.)
2. Generate `ctrl.*` from `ctrls.*` by a script `ctrlgenM1.py`,<sup>9</sup>  
Here `ctrl.*` is the main control file which contains all required information to perform calculations. `ctrl.*` contains not only the content of `ctrls.*`, but also other information needed for calculations. If necessary, we edit the generated `ctrl.*` file before next step.
3. Check crystal structure. `lmchk` is to confirm the crystal structure (space-group symmetry and so on). `lmchk` is applied not to `ctrls.*` but to `ctrl.*`. `ctrls.*` never used in the following steps.

**CAUTION for a known bug!** : If a crystal structure is only slightly different from a structure with higher symmetry, the `lmchk` may give a wrong crystal symmetry. In such a case, you have to “standardize structure” by VESTA or some other tools. This occurs e.g., when we use a structure numerically relaxed by VASP.

4. Run `lmfa` (calculations of spherical atoms (MT sites) in the cell). It also calculates core eigenfunctions and valence electron charge to set up initial condition. Then we run main calculation of LDA by `lmf`. It repeats iterations, and end up with converged results in LDA. Main result (electron density satisfying self-consistency) is stored in restart file `rst.*` (binary file). It finished within a second.
5. Run LDA/GGA calculations. We can run the LDA/GGA calculation by `lmf` or `lmf-MPIK` (-MPIK means kpoint parallel version).
6. Post processing.  
Plot energy band, DOS, PDOS, by running scripts. We can use scripts `job_band` for band plot (need `sym1.si` file (symmetry line for band plot)). We also have `job_pdos`, `job_tdos`, `job_fermi` and so on for DOS, PDOS, fermi surfaces. Since we use gnuplot to plot them, meanings of obtained data is apparently clear.

### 4.1 Write crystal structure file, ctrls

Let me show some samples of crystal structure files `ctrls.*`.

```
Cu: ~/ecalj/lm7K/TESTsamples/Cu/ctrls.cu
-----from here -----
% const da=0 alat=6.798
STRUC  ALAT={alat} DALAT={da}
        PLAT=  0.0 0.5 0.5    0.5 0.0 0.5    0.5 0.5 0.0
SITE    ATOM=Cu POS=0 0 0
-----to here -----
```

```
GaAs: ecalj/lm7K/TESTsamples/GaAs/ctrl.gaas
-----from here -----
#id = GaAs
%const bohr=0.529177 a=5.65325/bohr
STRUC
```

---

<sup>9</sup>`ctrlgenM1.py` exists originally at `ecalj/lm7K/` (`ctrlgenM1.py` was already copied to your `BINDIR=` defined in `ecalj/Install.ifort` in the installation).

```

        ALAT={a}
        PLAT=0 0.5 0.5 0.5 0 0.5 0.5 0.5 0
SITE
        ATOM=Ga POS=0.0 0.0 0.0
        ATOM=As POS=0.25 0.25 0.25
-----to here -----
SrTiO3: ecalj/lm7K/TESTsamples/SrTiO3/ctrls.srtio3
-----from here -----
%const da=0 au=0.529177
%const d0=1.95/au a0=2*d0 v=a0^3 a1=v^(1/3)
HEADER  SrTiO3 cubic
STRUC   ALAT={a1} DALAT={da}
        PLAT=1 0 0 0 1 0 0 0 1
SITE
        ATOM=Sr POS=1/2 1/2 1/2
        ATOM=Ti POS= 0 0 0
        ATOM=O POS=1/2 0 0
        ATOM=O POS= 0 1/2 0
        ATOM=O POS= 0 0 1/2
-----to here -----

```

Lines starting from '#' are neglected as comment lines. Lines starting from '% const' define variables and set values (in these cases, **da**, **alat**, and **bohr**, and so on). Then the variable **alat** is referred to as **{alat}**; in the cu case, **{alat}** means 6.798. Lines not start from '#' nor '%' are main content in **ctrls.\***.<sup>10</sup>

Note that we have two tags of "categories" "STRUC" and "SITE". ("HEADER" tag is also; but it is just for user's memo shown in console output). These tags should start from the first column. Thus **ctrls.\*** is divided into multiple "categories". In a category, we have "tokens" such as ALAT, DLAT, PLAT. These under STRUC category. ALAT+DALAT specify unit of length in this ctrl file. These are in a.u. (= bohr radius=0.529177Å).

The unit cell is given by PLAT (as noted, ALAT+DALAT as unit). In the above example of GaAs, three primitive cell vectors specified by nine numbers after PLAT=; they give three primitive vectors; PLAT1=(0,0,0.5), PLAT2=(0.5, 0.0, 0.5), and PLAT3=(0.5, 0.5, 0). DALAT is convenient to change lattice constant; but it is fixed to be zero here; thus no effect in this example.

Note that SITE category can have multiple ATOM tokens. The number of ATOM token under SITE should be the same as number of atoms in the primitive cell. In the case of GaAs; SITE contain multiple ATOM tokens. POS= just next to ATOM is taken as subtokens under ATOM token.<sup>11</sup> In cases, we specify such subtokens as SITE\_ATOM\_POS.

In the SITE category, we place atoms (MT names) in the primitive cell. In these cases we use defaults atomic symbol (MT names) for ATOM. POS is in the Cartesian coordinate (in the unit of ALAT+DALAT).

To test ecalj, you may make a test directory and copy a **ctrls.\*** to your directory. If you have VESTA and ecalj/StructureTool/ installed, you can see its structure by

```
$ viewvesta ctrl.s.cu
```

(here \$ means command prompt).

NOTE: As written in ecalj/README, you have to install VESTA and **viewvesta**. Then set VESTA= at the top of ecalj/Structure/viewvesta, and make softlink to it. The command **viewvesta**(~/ecalj/StructureTool/viewvesta.py) generate **POSCAR\_cu.vasp** first, then send it to VESTA. **viewvesta** also accept **POSCAR\_cu.vasp** directly. Except names starting from **ctrl** and **ctrls**, **viewvesta** sends the name to VESTA directly. We need extension '.vasp' to recognize it is written in VASP

<sup>10</sup>For these variables, we can overlay values when we start programs. For example, 'lmf -vdalat=0.1 si' means that **alat** is recorded in save.si file.

<sup>11</sup>This may looks slightly uncomfortable since the end of range of ATOM is not clearly shown; it end just at the next ATOM token or new category.

format. We have samples in `~/ecalj/StructureTool/sample`.

A tool `vasp2ctrl` converts POSCAR..vasp to ctrls.. “-help” show a small help.

- `ecalj/StructureTool/` is not tested well. Not believe it so much... We will fix it on your request. Another possible way is using `cif2cell`.

If you have a cif file, run

```
cif2cell foobar.cif -p vasp --vasp-cartesian --vasp-format=5
```

And convert POSCAR to ctrls. `cif2cell` is available from github.

In `ctrls.srtio3`, we use an expression `1/2` to give POS. We can use mathematical expression instead of values. Mathematical expressions such as “+ - \*/ sqrt(...)” are recognized. (instead of `3**2`, use `3^2`. Use parenthesis, and no space for an expression). We can use default atomic symbols (to check default atom name (MT name) type `ctrlngenM1.py --showatomlist`). Instead of such default symbols, we can use your own symbol as

```
SITE
  ATOM=M1 POS=1/2 1/2 1/2
  ATOM=M2 POS= 0 0 0
  ATOM=O POS=1/2 0 0
  ATOM=O POS= 0 1/2 0
  ATOM=O POS= 0 0 1/2
SPEC
  ATOM=M1 Z=38
  ATOM=M2 Z=22
  ATOM=O Z=8
```

. Then we have to add extra category SPEC where we set Z number. (You can use `Z=37.5` for virtual crystal approximation, however, you can not do it in ctrls now. Edit it in ctrl file. Such a procedure will be explained in other place.xxx)

This is an example for Antiferro NiO:

```
#id = NiO
%const bohr=0.529177 a=7.88
STRUC ALAT={a} PLAT= 0.5 0.5 1.0 0.5 1.0 0.5 1.0 0.5 0.5
SITE ATOM=Niup POS= .0 .0 .0
      ATOM=Nidn POS= 1.0 1.0 1.0
      ATOM=O POS= .5 .5 .5
      ATOM=O POS= 1.5 1.5 1.5
SPEC
  ATOM=Niup Z=28 MMOM=0 0 1.2 0
  ATOM=Nidn Z=28 MMOM=0 0 -1.2 0
  ATOM=O Z=8 MMOM=0 0 0 0
```

In this case, we define Niup and Nidn sites. These are recognized as Ni atom because of given Z number in SPEC. The subtoken `MMOM=Ms,Mp,Md,Mf...` re to specify number of magnetic moments ( $\mu_B$ ) for s,p,d,f channels (difference of up - down electrons within MT sites) as initial condition. In this case, we set `n(up)-n(down)=1.2` for Niup site for d channel. Even just one ATOM name is given by yourself, all ATOM in SPEC should be given (in this case SPEC for O should be given).

We can see other samples in `~/ecalj/lm7K/TESTsamples/*/ctrls.*`. (we also have a sample generator. See later section.) Note that ctrls file is jut in order to generate default ctrl file in the followings. Not from ctrls but from ctrl, we can start calculations. (thus ctrls is not needed if we prepare ctrl file directory).

It is possible to add `RELAX= 0 0 1` after `SITE_ATOM_POS`; this means structure relaxation along z-axis (also need to set DYN category as seen at <http://titus.phy.qub.ac.uk/packages/LMTO/tokens.html#DYNcat>), but its defaults are given (but commented out) automatically in the ctrl file generated by the procedure described in the following section). We detail it in other place xxx.

After `ctrl.*` is generated as shown below, we can run a command `lmchk` to check whether crystal structure is correctly given or not. It finishes in a second. It shows symmetry information, and so on used in the calculation.

**CAUTION!:** Positions of atoms are not necessarily fixed by `ctrl.*` when you restart calculation with `rst.*` file, because atomic positions are read from `rst.*`. We need to pay attention when we use DYN option because `lmf` run may save relaxed atomic positions into the `rst.*`. As “`lmf -help`” shows, `lmf si --rs=1,1,1,0,0` can read atomic position from `ctrl` file.

## 4.2 Generate default ctrl from ctrls by ctrlgenM1.py

To run programs of `lm7K` (`lmfa`, `lmf`, `lmchk`) in `ecalj`, we need an input file `ctrl.*`, which contains not only structures but also other settings. To generate `ctrl.*` from `ctrls.*`, we have a command “`ctrlgenM1.py`” (written in python 2.x and call fortran programs(`lmfa`,`lmchk`) internally). Two steps required to complete `ctrl` file: (i) we give reasonable options when we run `ctrlgenM1.py`. Then (ii) we may edit the `ctrl` file afterward. In anyway, `ctrl` file is the starting point of calculations; `ctrls` is required just in order to generate `ctrl`.

At first, try `ctrlgenM1.py` without arguments. It shows help. To generate `ctrl` from `ctrls`, type

```
$ ctrlgenM1.py cu --nk1=8
```

Here `cu` specifies `ctrls.cu`. The option `--nk1=8` means the number of division of the Brillouin zone for integration. It means  $8 \times 8 \times 8$  division. If we like to use  $8 \times 8 \times 4$ , we have to supply three arguments `--nk1=8 --nk2=8 --nk3=4`. The above command gives following console output.

```
$ ctrlgenM1.py cu --nk1=8
=== INPUT arguments (--help gives default values) ===
--help      Not exist
--showatomlist  Not exist
--nspin=1
--nk=8
--xcfun=vwf    !(bh,vwf,pbe)
--systype=bulk !(bulk,molecule)
--insulator   Not exist !(do not set for --systype=molecule)

...
```

OK! A template of `ctrl` file, `ctrlgen2.ctrl.cu`, is generated.

As we see above, options which you specified are shown at the beginning of the console output (in this case `--nk1=8`). Others such as `--nspin=1` are default settings. If we like to perform spin-polarized calculations, we add other option “`--nspin=2`” as

```
ctrlgenM1.py nio --nspin=2 --nk1=6
```

(NOTE: In the spin-polarized case, we need to set initial condition of size of magnetic moment at each atoms. Set it in `ctrls.*` as in the previous section, or edit MMOM of `ctrl` file (MMOM=`s p d f ...`) to be like MMOM=`0 0 1.2`). The `ctrlgenM1.py` generates `ctrl` file named as `ctrlgenM1.ctrl.cu`. To do calculations, copy it to `ctrl.cu` so that `lmf` can recognize it.

```
cp ctrlgenM1.ctrl.cu ctrl.cu
```

## 4.3 crystal structure checker: lmchk

Do `lmchk` to confirm that we can let `lmf` know correct crystal structure. It also shows crystal structure information, equivalent sites, site index and so on.

```
lmchk --pr60 cu (--pr# gives more informations if # is number)
```

Then it reads `ctrl.cu`. `--pr60` is an option of verbose. Bigger number gives more information.

- Lattice info, Space group symmetry operations (in `lmf` format), and their generators (these operations can be generated from a few of them.)

See <http://titus.phy.qub.ac.uk/packages/LMTO/tokens.html#SYMGRPcat> about how to represent the operations.

- Show atomic positions in ctrl file.
- Tabulate MT radius and distance between atomic sites.

(lmchk -help shows help, but difficult to see. Not need to read it first.)

lmchk is also shows atom (MT site) id (position and class(equivalent positions)). This is needed to interpret PDOS.

**CAUTION for a known bug! See 3 in Sec.4.:**

## 4.4 ctrl file

It is not necessary to look into ctrl file first, although some details are explained in the generated ctrl file. Please compare obtained results by lmf with those by other packages or literatures; let me know if you find something strange or your questions.

It is necessary to edit ctrl file to use full ability of lmf. For example, LDA+U, atomic position relaxation, core level spectroscopy, Change setting of default MTO and lo, better mixing procedure for stable convergence; higher accuracy, and so on.

But a few of ctrl file is easy to modify. Search these words and read explanations embedded in ctrl file.

(1)XCFUN

(choice of XC—it is not need to repeat ctrlgenM1.py). It is also possible to change number of k points for sampling, to modify crystal structure slightly, and so on; all things needed are in ctrl. It is not needed to repeat ctrlgenM1.py again.

(2)SO

To obtain correct dispersion around top of valence at  $\Gamma$  point for GaAs, we need to set SO=1 and NSPIN=2. QSGW calculation (by **gwsc**) do not allow this option now; Thus we run **lmf** (or **lmf-MPIK**) with such settings changed in ctrl file, after QSGW is converged.

lmf --input shows what can we write in ctrl file. But more than half are not for users, but for developers (or irrelevant now).

## 4.5 Run LDA/GGA calculations, and get convergence

Here we show how to get converged results from a ctrl file.

At first, we need initial guess of charge density. It can be given by a super position of atomic charge density. To obtain the charge density, we solve atoms first. It is by

```
$ lmfa gaas | tee llmfa
```

It takes just a few seconds. Here tee is a command of Linux. It keeps console output (standard output) to a file (llmfa in this case).

Then try

```
$ grep conf llmfa
```

. Then you see a key point that

```
conf:SPEC_ATOM= Ga : --- Table for atomic configuration ---

```

conf:      1  3      4  0      0.000  0.000 =>
conf:      1  4      5  0      0.000  0.000 =>
conf:-----

```

This is an initial electron distribution, and how we divide core and valence. In this case core charge  $Q_{\text{core}}$  are “6 electron for s channel=1s,2s,3s and 12 electron for 2s and 3p”.  $Q_{\text{core}}$  is treated by frozen core approximation. See Sec.2.5 in Ref.???.  $Q_{\text{val}}$  means electrons for valence s,p,d channels. The valence channels are 4s,4p,4d,4f (if we set EH=s,p,d,f) in this case The int(P)z column is for local orbital. Thus we have 3d treated as local orbital. (ecalj allow add one local orbital per  $l$ .)

The isp index means spin (1 or 2), since  $-n\text{spin}=1$  (when we invoke ctrlgenM1.py) for GaAs, no  $\text{isp}=2$  exist. In summary we have 4s,4p,4d,3d,4f as valence. This means we use corresponding number of MTOs and local orbitals.

After lmfa, let us start main calculation.

```
$ lmf cu
```

In unix, we can save console output to llmf by `$ lmf cu | tee llmf`. As it starts iteration calculations, it shows similar output again and again (it is a little too noisy now). Then you end up with self-consistent result as

```

.....
it 8 of 30 ehf= -3304.895853 ehk= -3304.895853
From last iter ehf= -3304.895856 ehk= -3304.895855
diffe(q)= 0.000003 (0.000007) tol= 0.000010 (0.000010) more=F
c ehf=-3304.8958531 ehk=-3304.8958529
Exit 0 LMF
CPU time: 7.024s Mon Aug 19 02:03:19 2013 on

```

it 8 of 30 means it stop at 8th iteration, although we set maximum number of iteration 30. Note that this number is given by `ITER_NIT=30` in `ctrl.cu`. ehf and ehk are the ground state energy in Ry. They are calculated in a little different procedure. Although they are different during iterations, it finally get to be the almost the same number. (But they can be slightly different even converged for large systems. But you don't need to care it so much).

NOTE: ehk:Hohenberg-Kohn energy, ehf: Harris-Faulkner energy.

“grep diffe llmf” shows how the changed of total energy (and charges) during iteration. diffe mean changes of energy with previous iteration, (q) is for electron density difference as well. See also save.\* file, which only show ehk and ehk obtained by each iteration.

“grep gap llmf” shows how the band gap changes (in the usual setting), two same numbers per iteration are shown now.

Thus we do have ground state energy. Although output of lmf is long, most of all are to monitor convergence (we will shrink it). As long as it converged well, you don't need to look into it in detail. Eigenvalues are shown as

```

bndfp: kpt 1 of 4, k= 0.00000 0.00000 0.00000 ndimh = 122
-1.2755 -1.2008 -1.2008 -0.2052 -0.2052 -0.2052 -0.0766 -0.0766 -0.0766
-0.0174 -0.0174 -0.0174 0.1094 0.1095 0.1095 0.2864 0.2864 0.4170
0.4170 0.4736 0.6445 0.6445 0.6445

```

This is at  $k= 0.00000 0.00000 0.00000$  . (because of historical reason, two same bndfp: are shown in each iteration; two band path method). “lmf cu| grep -A6 BZWTS” shows the Fermi energy (for insulator, we see band gap). Deep levels which gives little dependence on  $k$  are core like levels. These are in Ry; zero level is not so meaningful (for convenience, it is simply determined from the potential at MT boundaries).

rst.\* contains is the main output which contains electron density. mix.\* is a mixing file (which keeps iteration history). When you restart lmf again, it read rst.cu and mix.cu. If you start from lmfa result, please remove them. We can do parallel calculation with lmf-MPIK, we can invoke it with `mpirun -np 8 lmf-MPIK cu`. It should give the same answer.

## 4.6 DOS, Band, PDOS plot

We already have script to plot dos, band, and pdos from the result of lmf self-consistent calculations. We have scripts

```
job_tdos, job_band, job_pdos
```

. Look into these scripts, and then you see how to plot them.

For total DOS plot, it is better to check ctrl file; **BZ\_TETRA=1**(this is default; thus make sure that **BZ\_TETRA** do not exist or **BZ\_TETRA=1**). In addition, it might be better to enlarge number of k point **NKABC** in ctrl file to have smooth curve. Then we do

```
job_tdos cu
```

This shows total DOS as The range of DOS and division of total DOS is given by DOSMAX

Figure 1: DOS(Cu)

and NPTS in ctrl. Edit tdos.cu.glt for gnuplot for your presentation. Please look into **job.tdos** file in your bin directory. It is a small script.

For band plot, we have to set symmetry lines along which we plot eigenvalues. Collections **sym1.\*** are in **ecalj/MATERIALS/**. Choose and modify one of them and rename it. I will gather other samples soon. 'BZ wikipedia' or something else will help you to interpret it.

To do band plot, we need **sym1.cu** in your directory.

```
$ cp ~/ecalj/MATERIALS/Cu/sym1.cu .
```

Then check **sym1.cu**; it is

```
21 .5 .5 .5 0 0 0 L Gamma
21 0 0 0 1 0 0 Gamma X
0 (this is the terminator line)
```

We supply ten data for each lines (integer, three real, three real, two words). First line means, we calculate eigenvalues for **k** points from **k**=(0.5,0.5,0.5) to **k**=(0,0,0). "L Gamma" are names of two end points (.5 .5 .5) and (0 0 0) in this case. These names are used in a gnuplot script for band plot (**bndplot.isp\*.glt**). Second line means, we calculate eigenvalues for **k** points from **k**=(0,0,0) to **k**=(1,0,0). 3rd line means calculation just stop here. Units of **k** are in  $2\pi/\text{ALAT}$  (or  $2\pi/(\text{ALAT}+\text{DALAT})$  if **DALAT** exist.). A line starting from '#' is neglected (comment line).

To do band plot, run

```
$ job_band cu
```

. This is for both **nspin=1** and **nspin=2** (These scripts try to determine the Fermi energy first. You may skip it in cases (but need to change the script)).

For PDOS plot,

```
job_pdos cu
```

It shows figures (number of figures are number of atoms in the cell) in gnuplot (they are written in the same position on X-window; move top one a little). The command **job\_pdos** is a little time-consuming because we use no symmetry to distinguish all lm channels. (PDOS is not yet implemented for **SO=1** case; spin-orbit coupling  $L\hat{S}$  is added.) We can edit script of gnuplot (**pdos.site\*.glt**) for your purpose. To plot again, run

Figure 2: band plot(Cu)

```
gnuplot -persist pdos.site001.cu.glt
```

In principle, meanings of all data files are shown (see at the bottom of console output about lm ordering in a line), thus not so difficult to rewrite \*.glt. For example, to plot eg and t2g separately. (NOTE: site id is shown by lmchk).

**WARNING:** Usually lmf and so on recognize options such as -v option. For example, 'lmf gaas -vnspin=2' or 'lmf gaas -vso=1'. This option changes values of variables defined in % const section. This is recorded in save.\* file, and also shown at the top of console output. However, job\_tdos and so on, do not yet accept these options. Thus we need to modify ctrl file without using -v option. Or you need to write these option to these command by hand (we will fix this problem in future.)

## 4.7 Useful samples: ecalj/MATERIAL/

Not only ecalj/lm7K/TestSamples (some of them are by older version), We have a material database in ecalj/MATERIALS/. Move to the directory, and type

```
$ ./job_materials.py
```

Then it shows a help. You see

```
...
=== Materials in Materials.ctrls.database are:===
2hSiC 3cSiC 4hSiC AlAs AlN AlNzb AlP AlSb Bi2Te3 C
CdO CdS CdSe CdTe Ce Cu Fe GaAs GaAs_so GaN
GaNzb GaP GaSb Ge HfO2 HgO HgS HgSe HgTe InAs
InN InNzb InP InSb LaGaO3 Li MgO MgS MgSe MgTe
Ni NiO PbS PbTe Si SiO2c Sn SrTiO3 SrVO3 YMn2
ZnO ZnS ZnSe ZnTe ZrO2 wCdS wZnS
...
```

. For these simple materials (now 57 materials), input files can be generated, and run them automatically by a command ./job\_materials.py below. The ctrls are stored in ecalj/MATERIALS/Materials.ctrls.database in a compact manner (in addition, options passed to ctrlgenM1.py and options to lmf-MPIK are included). See ecalj/MATERIALS/README about how to add new material to it; it is not difficult. The command ./job\_materials.py gives ctrls.\* for these materials from descriptions in the Materials.ctrls.database. And then it generates ctrl file by calling ctrlgenM1.py internally, and run lmfa lmf-MPIK successively (when no -noexec).

Try `./job_materials.py Fe --noexec`. (not fe but Fe as it shown above) at `ecalj/MATERIALS/`. Then it makes a directory `Fe/` and set `ctrl.fe` (also `ctrls.fe`) in the directory. Without `'--noexec'`, it does calculation for Fe successively. As for NiO and Fe, we see that `./job_materials.py` gives `SPEC_ATOM_MMOM` in generated `ctrls` and `ctrl` files. (Look into `ctrls.fe`; we need `SPEC` section when we add `MMOM`.)

Try `job_materials.py GaAs Si`.

Then directories `GaAs/` and `Si/` are generated. See `save.*` files containing total energies iteration by iteration. Starting from `ctrl.*` in these directory, the command perform DFT calculations (Console output is stored in `llmf`, `save.*` gives total energies. `rst.*` contains self-consistent density, from which we can calculate energy bands and so on).

`./job_materials --all --noexec` generates `ctrls` and `ctrl` files of these materials. `./job_materials --all` do self-consistent LDA calculations for materials (it takes an hour or more. To change the number of cores for `lmf-MPIK`, set option `-np` (number of core). See help of `./job_materials` (type this without arguments).

To make band plot and so on for Fe, follow instructions already explained.

```
$ ./job_materials.py Fe (and need to type return)
(If you like start over, remove Fe/ under it first).
$ cd Fe
$ ./job_materials.py fe
  (but it might be better to do --noexec, and observe Fe/ctrls.fe and
Fe/ctrl.fe first. grep conf llmf shows the initial electron distribution).
$ cat save.fe (this shows total energies of each iteration. 'c ' at
the first column gives converged result. 'h ' is from atm file.)
  If it does not ends with 'c ...' line, something strange
occurs. see llmf (console out put of lmf is saved to llmf).
$ cp ../syml.fe .
$ job_band fe -np 4
  (As I said, this shell script do not yet accept
options to lmf. Look into the script).
  (This calculate fermi energy first for safe; it takes
some time)
$ job_tdos fe
$ job_pdos fe (as I said, this supress space-group symmetry, thus time consuming).
```

At the end of `job_pdos`, we show a help which `pdos` data is where (In `pdos` file, we have 26 numbers a line; first is energy, 2-26 are `pdos` for `s,p,d,f,g`; which is which are shown in the help). See `joblmf` file also (it contains options to invoke `lmf`. This is shown in `save.*`. In principle, options in `joblmf` should be passed to band plot and so on. But not yet implemented (it is not so difficult; I have to do it).

After doing `./job_materials foobar`, you may like move it back to original... In such a case, `git` works. At `ecalj/`, do

```
$ mv MATERIALS MATERIALS.bk
$ git checkout MATERIALS
```

Then you can see `MATERIALS/` is moved back to just downloaded one.

## 4.8 How to add spin-orbit coupling?

In the LDA level calculations, we can use `S0=0` (no `S0`), `S0=1`(`LdotS`), or `S0=2`(`LzSz`) schemes. However, `S0=1` is not the non-collinear method (`z`-direction is assumed to be spin direction; in cases we may need to primitive cell so that the `z`-direction is the spin direction).

Within LDA, we have two possible ways.

(A) Do LDA and/or QSGW with  $S0=0$  first.  
 Then apply the spin-orbit coupling by perturbation.  
 or (B) do self-consistent LDA calculations with  $S0=1$  (or  $=2$ ).  
 For semiconductors, we think you observe little differences.

Let me explain the case (A).

After converged with  $nspin=1$ , create new directory and copy

```
ctrl.gas, rst.gas, sigm.gas, QGpsi,
to it. Then we set
nspin=2
METAL=3 (usually this is default)
S0=1 (this is ldots calculation off-diagonal elements included).
Q=band (we do not change potential.)
```

in ctrl.gas.

Then run

```
>lmf gas >& llmf_S0
```

You can see "band gap with  $S0$ " by

```
> grep gap llmf_S0.
```

Then you can see two same lines.

```
VBmax = 0.101949 CBmin = 0.236351 gap = 0.134402 Ry = 1.82786 eV
VBmax = 0.101949 CBmin = 0.236351 gap = 0.134402 Ry = 1.82786 eV
(two lines per iteration is shown in metal mode).
```

This is the band gap with  $S0$  as a first-order perturbation  
 on top of the "QSGW without  $S0$ ". When you use ctrl file generated by  
 ctrlgenM1.py. You can do the above procedure with

```
>lmf --rs=1,0 gas -vnit=1 -vso=1 -vnspin=2 -vmetal=3 --quit=band
(--rs=1,0 read rst.gas but not write rst.gas. Run lmf --help.
The switch -v (-vso=1 in this case) replaces so=0 with so=1.
This is recorded in save.gas file).
```

For band plot, you can use the same procedure

for the case without  $S0$ . (Look into the shell script job\_band.

You have to modify it so that

```
'--rs=1,0 gas -vnit=1 -vso=1 -vnspin=2 -vmetal=3 --quit=band'
is added to arguments for >lmf --band:sym1 ...).
(--quit=band is not necessary if we like to renew eigenfunctions
self-consistent. Anyway we expect little differences.)
```

---

\noindent QSGW with  $S0$ :\\

For given sigm file, it is possible to attain self-consistency with  $S0=1$ (or $=2$ ) with keeping sigm (the  
 However, this imply that  $V_{xc}$  is fixed in QSGW,  
 it is not necessary better than the above procedure.

## 4.9 PROCASR (VASP format) generator

PROCASR mode for lmf (not yet in lmf-MPIK) Band weight decomposition. (Size of circles  
 show the size of components. Superposed on band plot). See ecalj/MATERIALS/MgO\_PROCAR/README,  
 May19.2014

## 4.10 efermi.lmf

This is generated by lmf(lmf-MPI), which is used in the job\_band.

## 4.11 Effective mass calculation

New band plot and effective mass calculation (curvature):  
(see sample at ecalj/MATERIALS/mass\_fit\_test/ and its README).

-----

We now read sym1.\* in lm7K/fp/bndfp.F. Thus job\_band is changed  
(nspin=1 or nspin=2 is automatically choosed by job\_band command).  
We do not use plbnd anymore. If necessary, you can modify  
"writeband" subrouitne in lm7K/fp/bndfp.F by yourself.

Follow step to get effective mass...

1.

New sym1 read label of k point. It is shown by the gnuscript  
file "bandplot.glt". Type "gnuplot -p bandplot.ispl.glt" and so on,  
when you like to remake band plot.

2.

New sym1 allow a special input suitable to determine effective mass  
for semiconductor. An example of new sym1 is (this is a case of GaAs)

----- sym1 example start -----

```
5 0 0 0 .5 .5 .5 Gamma L
5 0 0 0 1. 0 0 Gamma X
5 0 0 0 .75 .75 0 Gamma K
#####
## resolution qinit qend iqinit iqend etolv(Ry) etolc(Ry) symllabels
## mass*.spin* contains bands which is evaltop-etolv < eband <econtop+etolc
-888 !note -888 start Mass line. Here is a ZB case
257 0 0 0 .5 .5 .5 1 32 0.1 0.01 Gamma L
257 0 0 0 1. 0 0 1 32 0.1 0.01 Gamma X
257 0 0 0 .75 .75 0 1 32 0.1 0.01 Gamma K
0 !terminator
----- end -----
```

New feature is start from next line to the -888 line.

257 means a line connecting 0 0 0 (Gamma) and .5 .5 .5 (L) is divided  
into 256. and we only calculate from the 1st point to the 16th point  
among 513 points (now we need to include 1st point for mass).

We only make "Band001Sym1005Spin1.mass" files which contains effective  
math along the line only near the Fermi energy, that is,  
we plot only bands whose energy E at Gamma (exactly speaking, at  
left-end point), is evaltop-etolv < E < econtop + etolc.

(As its head line shows, Band\*.mass file contains data

isym1,iq, ib,isp, QPE-EF, QPE-QPE(start), |q|, mass=2\*2\*(QPE-QPE(start))/|q|\*\*2).  
here QPE(start) is QPE at the left-end of sym line.)

For GaAs, please use this sym1, and run job\_band.

(e.g., job\_band gaas -np 2 -vnspin=2 -vso=1;

note that -vfoobar=xxx replace value of foobar with xxx in ctrl.gaas)

Then you can see not only bandplot.ispl.glt, but also

massplot.ispl.glt, which is to plot data related to the last 3 lines  
after -888. This is the effective mass plot for q points.

Note that what we need is at q to zero limit.

3. We have to make interpolation to q to zero.

In such a case, a possible way is "take average of degenerated bands,  
and make an interpolation (least square fit by gnuplot).

4. least square fit by gnuplot.

We have an example is at ~/ecalj/MATERIALS/mass\_fit\_test0.tar.gz  
Expand this gives mass\_fit\_test0/. Look into ./job and run it.  
See README in it.

----

For your convenience, we have dE/dk in the bnd\*.spin\* files.  
This is useful to determine the Fermi surface.  
See the efermi.lmf to read the Fermi energy.

## 4.12 LDA+U, partially occupied core-hole

See

file:///home/takao/ecalj/Document/BACKUP/MarksOriginalDoc/fp.html#ldaplusu

We need to add lines such as

IDU= 0 0 2 2 UH= 0 0 0.1 0.632 JH= 0 0 0 0.055

for each SPEC\_ATOM, And initial occnum.foobar file.

An example is in ecalj/MATERIALS/GdNldau/

When you just like to generate initial condition for gwsc,  
you have to remove (or comment out) IDU before the 1st iteration  
with sigm file, because sigm may already can contain LDA+U kind of effect.  
(Thus you may need to modify gwsc or stop it at the 0th iteration,  
and then remove IDU...)

Caution:

We need the initial condition file such as occnum.gdn for LDA+U.

(you may need to set "% real" at the begninig of the file).

Note that definition of spherical harmonics is in ecaljmanual.pdf.

(real harmonics is usual ones used in jobpdos).

Look for the keyword ldau in fp/lmfp.F -> sudmtu.F which read occnum.gdn.

## 5 How to run QSGW calculation?

In the QSGW, we calculate a *non-local exchange-correlation potential*  $V^{xc}(\mathbf{r}, \mathbf{r}')$ , by a procedure of GW calculation (very time-consuming part). Then difference  $V^{xc}(\mathbf{r}, \mathbf{r}') - V_{xc}^{LDA}(\mathbf{r})\delta(\mathbf{r} - \mathbf{r}')$  is stored into **sigm.\*** file. The potential file **sigm** is a key to perform QSGW calculations as seen in Fig.6. The **sigm** contains static non-local potential  $\Sigma_{QSGW} - V_{xc}^{LDA}$ .

Then, we again do one-body calculation by **lmf** (or **lmf-MPIK**) where we add this **sigm** to one-body potential ; when we run **lmf** or **lmf-MPIK**(k-parallel mpi version), **sigm** is read and added to the one-body potential if we have HAM.RDSIG=12 in ctrl.\*. Thus this means that we replace  $V_{xc}^{LDA}(\mathbf{r})\delta(\mathbf{r} - \mathbf{r}')$  with  $V^{xc}(\mathbf{r}, \mathbf{r}')$ .

This iteration cycle is performed by a script "gwsc" as we explain later on. (In the default setting of ctrl.\* file, lmf try to read sigm.\* file as long as it exists. If not, do lmf or lmf-MPIK calculation.

To start QSGW calculation by **gwsc**, we need not only ctrl.si, but also another input file **GWinput**. Its template **GWinput.tmp** can be generated by the Step.2 as follows.

As a summary, you have to follow steps below in order to perform QSGW calculation.

Step 1. Perform from the Step.1 thru the Step.4 (up to lmfa) in Sec.4.5. (as same as the case of LDA/GGA).

You don't need to perform LDA calculation in advance, since **gwsc** perform LDA/GGA calculation at its beginning. (It means that we start from the one-body Hamiltonian  $H_0$  in LDA/GGA as initial condition. In cases, LDA/GGA give poor initial conditions for QSGW; in such a case, we may need another trick to prepare starting point.).

[Caution: We have to use the same **LMXA** ( $l$  in the expansion of eigenfunctions in each MT) for all the MT spheres. (This is due to historical reason; we may need to fix this.)]

xxx need to explain **LMA** xxx

Step 2. Run the script **mkGWIN\_lmf2**.

The purpose of this script is to get **GWinput.tmp**. Other files generated are not used in the following stage.

Step 3. Edit **GWinput.tmp** and save it as **GWinput**.

**GWinput** is the input file describing the computational conditions for *GW* calculation. Usually, the default setting gives reasonable results. To reduce computational time, we may use **lcutmx(atom)=2** for oxygen sites (this may be also other small atoms.). **grep lcut GWinput -A1** shows **lcutmx** for each atomic sites) These step 2. and step 3. are just only to get **GWinput**.

Step 4. Run the script **gwsc**.

## 5.1 GWinput

In order to perform QSGW, one another input file **GWinput** (no extension) is necessary in addition to **ctrl.\***. Thus all input files for QSGW is just two files, **ctrl.\*** and **GWinput**. A template **GWinput** can be generated by a script **mkGWIN\_lmf2**. You may have to modify it in cases for your purpose.

Let us start from **ctrls.si**;

```
#id = Si
%const bohr=0.529177 a= 5.43095/bohr
STRUC
  ALAT={a}
  PLAT=0 0.5 0.5 0.5 0 0.5 0.5 0.5 0
SITE
  ATOM=Si POS=0.0 0.0 0.0
  ATOM=Si POS=0.25 0.25 0.25
```

. Do **ctrlgenM1.py si --tratio==1.0 --nk1=6** and copy **ctrlgenM1.ctrl.si** to **ctrl.si**. NOTE: the option **--tratio=1.0** means we use touching MT; this can be checked by **lmchk si**; since defaults is almost unity (**--tratio=0.97**), this is irrelevant, just to explain options.

We have to write **GWinput**. The default is given automatically by a command **mkGWIN\_lmf2**;

```
$ lmfa si (lmfa is needed to do in advance).
$ mkGWIN_lmf2 si
.....
== Type three integers n1 n2 n3 for Brillouin Zone meshing for GW! ==
n1=
```

Then it pause and ask numbers. You have to type three numbers as 2+ return + 2+return+2 return.

```
== Type three integers n1 n2 n3 for Brillouin Zone meshing for GW! ==
n1= 2
n2= 2
n3= 2
2 2 2
...(skip)...
OK! GWinput.tmp is generated!
```

Generated file is **GWinput.tmp**; you have to copy it to **GWinput**.

```
$ cp GWinput.tmp GWinput
```

These '2 2 2' you typed is reflected in a section 'n1n2n3 2 2 2' in GWinput. This means 2x2x2 (8 points in 1st BZ). You can edit it, and change it to e.g. 'n1n2n3 4 4 4' if you like to calculate self-energy on dense BZ mesh 8x8x8.

The template of GWinput is usually not so bad. But it may give a little expensive setting (or not very good enough in cases).

## 5.2 Run gwsc script

Let us perform QSGW calculation. For this purpose, we use a script `gwsc`. We need to do `lmfa` in advance. Then do (not need to do `lmf`);

```
gwsc (number of iteration+1) -np (number of nodes) (id of ctrl)
```

If (number of iteration+1)=0, it gives one-shot calculation from LDA. But it is different from the usual one-shot; since it calculates off-diagonal elements of self-energy also, we can plot energy band dispersion. In cases (for usual semiconductors), it can give rather reasonable results in comparison with experiments from practical point of view.

This is an example of one iteration of QSGW cycle. (now a little different but essentially similar)

```
takao@TT4:~/ecalj/test1$ gwsc 0 -np 2 si
gwsc 0 -np 2 si
### START gwsc: ITER= 0, MPI size= 2, TARGET= si
--- No sigm nor sigm.$TARGET files for starting ---
---- goto sc calculation with given sigma-vxc --- ix=,0
No sigm ---> LDA caculation for eigenfunctions
      Start mpirun -np 2 /home/takao/ecalj/TestInstall/bin/lmf-MPIK si > llmf_lda
OK! --> Start echo 0| /home/takao/ecalj/TestInstall/bin/lmf gw si > llmf gw0
OK! --> Start echo 1| /home/takao/ecalj/TestInstall/bin/qg4 gw > lqg4 gw

OK! --> Start mpirun -np 2 /home/takao/ecalj/TestInstall/bin/lmf-MPIK si > llmf_gwscend.0
OK! ==== All calclation finished for gwsc 0 -np 2 si ====
```

Here `echo (integer)` is readin in at the beginning of the code. To see it, please look into `gwsc` script (`gwsc` is at `ecalj/fpgw/exec/` and copied to your `bin/` by `make install2`). In anyway, this console output shows calculations finished normally.

Now we get `rst.si` and `sigm.si` file which contains (static version of) self-energy minimis  $V_{xc}^{LDA}$ . What we did is the one-shot GW from LDA result; but note that we calculate not only diagonal elements but also off-diagonal elements.

We can write energy dispersion (band plot) in the same manner in LDA. To do it, we need `rst.si`, `sigm.si`, `ctrl.si`, `QGpsi`. (but `QGpsi` is quickly reproduced). After you have `sym1.si` (e.g. in `ecalj/MATERIALS/`), Do

```
$ job_band si
```

Figure 3: Si, one-shot GW with off-diagonal elements

You can observe large band gap as shown in the Fig.5.2. (To see it again, `gnuplot bnds.gnu.si -p`. All plots are in gnuplot, thus it is easy to replot it as you like).

We have QPU file (and also QPD for spin=2), which contains content of the diagonal part of self-energy. It will be explained elsewhere.

You can make total DOS and PDOS plot by

```
$ job_tdos si
$ job_pdos si
```

CAUTION:pdos plot is not allowed for so=1. (even `tdos-l` ask to t.kotani.)

To get final QSGW results, we have to repeat iteration until eigenvalues are converged. Note that total energy shown by console output `llmf` (and also shown in save file) is not so meaningful in the QSGW; we just take it as an indicator to check convergence. Let us repeat 5 iteration more. `"-np 2"` means one core to use.

```
$ gwsc 5 -np 2 si
### START gwsc: ITER= 5, MPI size= 2, TARGET= si
--- sigm is used. sigm.$TARGET is softlink to it ---
---- goto sc calculation with given sigma-vxc --- ix=,0
we have sigm already, skip iter=0
---- goto sc calculation with given sigma-vxc --- ix=,1
...(skeip here) ...
```

OK! --> == 5 iteration over ==

OK! --> Start `mpirun -np 2 /home/takao/ecalj/TestInstall/bin/llmf-MPIK si > llmf_gwscend.0`

OK! ==== All calclation finished for gwsc 0 -np 2 si ====

Note that we do skip 0th iteration (it is for one-shot from LDA) since we start from `rst.si` and `sigm.si` given by one-shot LDA. Thus we do just five iterations. Information of eigenvalues are in `QPU.(number)run` files. (for magnetic systems with `nspin=2`), we have `QPD.(number)run` also). Check it by `ls`;

```
$ ls QPU.*run
QPU0.run QPU.1run QPU.2run QPU.3run QPU.4run QPU.5run
```

(These are overwritten when we again repeat `gwsc`; be careful.) Note that `QPU0.run` was old one when you did 1-shot GW from LDA at the beginning. In anyway `*.0run` are confusing files; remove them).

In order to check convergence calculations going well during iteration, do

```
$ grep gap llmf*
```

This shows how band gap changes in `lmf.*run` files. In metal cases, we need to compare QPU file, magnetic moment or `grep '[xc] save.*`; this shows end of lmf iteration. Energy is not so meaningful but can be indicator to convergence.

Let us check convergence of the QSGW calculations. For this purpose, it is convenient to take a difference of QPU(QPD) files by a script `dqpu`. These files are human readable. To compare `QPU4.run` and `QPU5.run`, do

```
$ dqpu QPU.3run QPU.4run
```

Then we see a list of numbers (these are the differences of values in QPU files). Then it shows at the bottom as

```
Error! Difference>2e-2 between:  QPU.4run  and  QPU.5run
:  sum(abs(QPU-QPD))= 0.05736
```

but you don't need to care it so much. You rather need to check the difference of values. I can say most of all difference (especially around the Fermi energy are ) are almost 0.00eV or 0.01eV, we can judge QPEs are converged. If not converged well, you may need to repeat `gwsc` again. (when the size of two QPU files are different, `dqpu` stops.)

Figure 4: band plot(Si, QSGW one-shot test) and band(Si) (GGA)

Figure 5: band(GaAs), QSGW (test case)

### 5.3 Spectrum function: How to calculate $\langle qn | \Sigma(\omega) | qn \rangle$

We have an example at `ecalj/MATERIALS/SiSigma/`, where you can just type `job`. It calls a shell script `gwsigma`, which is just a modification of `gwsc` for spectrum function plotting. If you have `sigm.*`, it will automatically read it as in the case of `gwsc`.

By the script `gwsigma`, we calculate the diagonal elements  $\langle \psi(\mathbf{q}, n) | \sigma_c(\omega) | \psi(\mathbf{q}, n) \rangle$ . Thus we need to set  $\mathbf{q}$  and band index  $n$  for which we calculate. In addition, we need to set resolution of  $\omega$ .

1. Set <QPNT> section. This section is to set the  $\mathbf{q}$  point, and band index for which we calculate the self energy. In addition, energy mesh for plotting is set.

(A) Set  $\mathbf{q}$  point set

If you set

-----

```
*** all q -->1, otherwise 0; up only -->1, otherwise 0
      1          0
-----
```

You will have self-energy for all irreducible  $\mathbf{k}$  points. This may be needed for  $A(\omega)$ .  
or

You have to set all  $\mathbf{q}$  points as

-----

\*\*\*  $\mathbf{q}$ -points, which should be in qbz., See KPNTin1BZ.

```
      3          <--- number of readin q point
```

```
1      0.0000000000000000      0.0000000000000000      0.0000000000000000 <--1st number is irrel
2     -0.5000000000000000      0.5000000000000000      0.5000000000000000
3      0.0000000000000000      0.0000000000000000      1.0000000000000000
-----
```

To know allowed  $\mathbf{q}$  points on regular mesh point, run the command "mkGWIN\_lmf2", then supply  $n_1, n_2, n_3$ . The template of GWinput.tmp contains all possible  $\mathbf{q}$  points. Edit it.

NOTE: Any  $\mathbf{q}$  option can allow you to specify any  $\mathbf{q}$  points by shifted mesh technique. (if necessary, but only for some special purpose).

(B) Band index set

It is specified by the section

-----

\*\*\* no. states and band index for calculation.

2

4 5

-----

means the self-energy for band index 4 and 5. Just two bands.

If you like to plot self energy from 1 through 8, use

\*\*\* no. states and band index for calculation.

8

1 2 3 4 5 6 7 8

-----

If you need 17 bands for example, it should be 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 in addition to 17 (number of bands at the first line).

(C) energy mesh set

At the bottom of <QPNT> section, we have

-----

\*\*\*\*\*

0.01 2.0

-----

Two real number should be supplied.

These are `dwplot` and `omegamaxin`, read in `hsfp0.m.F` by a line

```
read (ifqpnt,*,err=2038,end=2038) dwplot,omegamaxin
```

`dwplot` (=0.01 Ry) is mesh for self energy.

omegamaxin=(2.0 Ry) means the range "-2 Ry to 2 Ry" for self-energy plot.

Note that imaginary part of Sigma is given as the convolution of ImW(omega) and the pole of (esmr in GWinput gives energy smearing of the pole). Resolution for Im W (near omega=0) is b. I think that the resolution of self-energy is ~ 0.05 eV in the default setting. This is because  $\Delta\omega \sim \Delta\epsilon_{smr} \sim 0.05$  eV.

2 Run gwsigma. This will run

```
echo 4| mpirun -np 24 hsf0,
after dielectric function is calculated.
Then we have SEComg.UP (DN) files, Look for file handle, ifoutsec,
for the file in fpgw/main/hsfp0.m.F to see format for the file.
(not hsf0.sc.m.F but hsf0.m.F). Search a line
open(ifoutsec,file='SEComg'//sss) (around hsf0.m.F L1052)
You can find that we use following lines to plot SEComg.*.
-----
      write(ifoutsec,"(4i5,3f10.6,3x,f10.6,2x,f16.8,x,3f16.8)")
&      iw,itq(i),ip,is, q(1:3,ip), eqx(i,ip,is),
&      (omega(i,iw)-ef)*rydberg(), hartree*zsec(iw,i,ip) !,suming
This means we use energy in eV.
iw:      omega index
itq(iq): band index specified by <QPNT>
ip:      k point index specified by <QPNT>
is:      spin index
q:      q vector (cartesian in 2pi/alat)
eqx:     eigenvalue in eV. (I think relative to the Fermi energy)
(omega(i,iw)-ef)*rydberg(): omega relative to the Fermi energy
hartree*zsec(iw,i,ip):      Self energy. real and imaginary part.(complex, two values)
```

You can only repeat echo 4| mpirun -np 24 hsf0  
when you change setting in <QPNT> section.

3 Example. There is an example MATERIALS/SiSigma/

```
plot 'SEComg.UP' u ($9):($10) w l,' ' u ($9):($11) w l
can give a plot for Re (Sigma_c(omega)) and Im(Sigma_c).
```

```
9th: energy in eV      (omega(i,iw)-ef)*rydberg()
10th: real part        Re hartree*zsec(iw,i,ip)
11th: imag part        Im hartree*zsec(iw,i,ip)
```

4 To get integrated spectrum function (DOS), we need to superpose all the spectrum function (All q points and all band index). Be careful about the degeneracy (multiplicity) for each q points. You have to build it from SEComg file. To know the multiplicity, search following lines of keyword Multiplicity in the console output of qg4gw (lqg4gw).  
Anyway, consider about "is it worth to do?" To confirm your result, use sum rule (sum of spectrum weight). And pay attention to the relation between real and imag parts (Hilbert transformation).

## 6 gwsc script to perform QSGW

### 6.1 outputs of gwsc

Figure 6: Shell script `gwsc` to perform QSGW contains an iteration loop to make `sigm` (and eigenvalues, eigenfunctions) self-consistent. The iteration loop is written in `ecalj/fpgw/exec/gwsc` (a bash script). Exactly speaking, we have to pass all the required data (not only eigenvalues and eigenfunctions, but also crystal structure,  $\mathbf{q}+\mathbf{G}$  vectors, symmetry information and so on) to `GW part`. The purpose of the `GW part` is to calculate  $\Sigma_{\text{QSGW}} - V_{\text{xc}}^{\text{LDA}}$ .

When `gwsc` runs normally, it gives console output as follows. This is a case for `ctrl.gaas` for

```
>gwsc 10 -np 24 gaas
. Without arguments, typing gwsc shows usage as
>An example of usage: gwsc 5 -np 4 si, where 5 means 5+1 iterations
. We recommend you do look into the script gwsc. It uses run_arg, which is a special subroutine
of bash; but not so difficult to understand it. (In the followings, we assume /home/binx/ is
your bin directory at which we have all binaries for ecalj.)

### START gwsc: ITER= 10, MPI size= 24, TARGET= gaas
--- No sigm nor sigm.$TARGET files for starting ---
---- goto sc calculation for given sigma-vxc --- ix=,0

OK! --> Start echo 2 | mpirun -np 24 /home/binx/hsfp0_sc > lsc
OK! --> Start echo 0 | /home/binx/hqpe_sc > lqpe
OK! --> Start echo --- | mpirun -np 24 /home/binx/lmf-MPIK gaas > llmf_oneshot
... (this is the end of main stage) ...
== 0 iteration over ==
---- goto sc calculation for given sigma-vxc --- ix=,1
OK! --> Start echo --- | mpirun -np 24 /home/binx/lmf-MPIK gaas > llmf
OK! --> Start echo 0 | /home/binx/lmfgw gaas > llmfgw00
... (lines here omitted) ...
OK! --> Start echo 0 | /home/binx/hqpe_sc > lqpe
== 1 iteration over ==
... (lines here omitted) . . .
== 2 iteration over ==
... (this repeat until ITER= 10(the first argument to gwsc) ) ...
```

This shows that **gwsc** invoke **lmf-MPIK**, **lmfgw**, **qg4gw**, ... successively. **echo 3|hbasfp0** means running a fortran program **hbasfp0** with the argument '3' from the standard input (**read(\*,\*)** in fortran code). We can divide these successive calls to “preparation stage” and “main stage”. Preparation stage is just to prepare eigenfunctions and so on which are required for the “main stage” of GW calculation. At the end of “main stage”, we have the potential file **sigm**.

As it shows, console output are going to **l\*** files.

## 6.2 Preparation stage of gwsc

At the end of this stage, we get required eigenfunctions, BZmesh data, and so on, which are required for the main stage. Note that **echo 0 | lmfgw** means supply an integer to the fortran program **lmfgw** from standard input by **read(\*,\*)**.

- **lmf-MPIK** (k-parallel version of **lmf**)  
This is the one-body calculation for given **sigm.gaas**. At the beginning, we do not have **sigm.gaas**. In this case **lmf-MPIK** just perform LDA/GGA calculation.
- **echo 0 | lmfgw**:  
Get some small information files to start **qg4gw**. If you type just **lmfgw**, and observe what occurs. It shows a menu and pauses (asking you to supply an integer); then we supply 0 in this case. (If we do **echo 0 | lmfgw**, no pause occurs.)
- **echo 1 | qg4gw** : Get **k** points used in the *GW* calculations and the corresponding **G** vectors. And what is the irreducible k point (See console output of **qg4gw**. **gwsc** keeps it in **lqg4gw**).  
Since we use the offset-Gamma method for BZ integration for  $G \times W$ , we need shifted mesh points to calculate *W* at offset-Gamma points. The **q** vectors of offset-Gamma method is in **Q0P** file. (If you have two points in **Q0P**, we see two shifted mesh points in addition to regular mesh points.) Remember that cutoff of **G** is given by **QpGcut\_psi** and **QpGcut\_cou** in **GWinput**. (Based on the experiences, we use smaller **QpGcut\_cou** to reduce computational time. Explained in other section xxx).
- **echo 1 | lmfgw-MPIK** : Calculate the LDA eigenfunctions, eigenvalues, and  $\langle \psi | V_{xc}^{LDA} | \psi \rangle$  at the irreducible **k** points (shown at the bottom of output **lqg4gw** of **qg4gw**.)
- **lmf2gw**: store these data into **DATA4GW\_V2** and **CphiGeig**, whose I/O is controlled by a key subroutine **gwinput\_v2.f**.

## 6.3 Main stage of gwsc

We can start the main stage of *GW* calculation from these files;

**GWinput DATA4GW\_V2 CphiGeig QGpsi QGcou Q0P QIBZ SYMOPS BZDATA HAMindex CLASS**;  
these files contains eigenfunctions and so on in the manner of Eq.(17) of [2], eigenvalues and other required information. This is the starting point of the *GW* calculation.

- **GWinput** : computational conditions.
- **DATA4GW\_V2** : Crystal structures and so.
- **CphiGeig** : Eigenvalues and Eigenfunctions
- **QGpsi** : **q** and **G** vector for the eigenfunctions(**q** means **k** in the previous section),
- **QGcou** : **q** and **G** vector for the Coulomb matrix
- **Q0P** : **q** points near **q=0** instead of **q=0** (offset Gamma points)
- **QIBZ** : irreducible **q** points (This is also contained in **BZDATA**).
- **SYMOPS** : point group operation
- **BZDATA** : **q** points date (and tetrahedron weights if necessary) for BZ integrals.
- **HAMindex** : Hamiltonian index, all required complex index for Hamiltonian of PMT method. (See the top of subroutine **write\_hamindex** in **lm7K/subs/m\_hamindex.F**. This is also in

fpgw/gwsr/m\_hamindex.F. Identical files are in two different directory— it should be avoided in future.)

- **CLASS** : class information or atomic sites (equivalent sites).

With these files, we do the main stage as

- **rdata4gw\_V2**: Read DATA4GW\_V2 and so on, and decompose it into files required in the followings. And calculate PPOVL\* files (overlap matrix of interstitial plane waves. Because of technical reasons some different types of PPOVL\* with **q**-point index).
- **heftet** : Get the Fermi energy **EFERMI** by tetrahedron method. It is used in **hx0fp0**.
- **hchknw** : stores the number of required  $\omega$  points along real-axis into NW. (NW is not essentially used, but is supposed to exist in the followings.)
- **echo 3|hbasfp0**: gives the product basis for Core exchange.
- **echo 0|hvccfp0**: gives the Coulomb matrix for the Core exchange.
- **echo 3|hsfp0\_sc** : gives the Core exchange part of the self-energy. <sup>12</sup>
- **echo 0|hbasfp0**: gives the product basis.
- **echo 0|hvccfp0**: gives the Coulomb matrix  $v$ .
- **echo 1|hsfp0\_sc** : gives the exchange part of the self-energy.
- **echo 11|hx0fp0\_sc** : gives the correlated part of the screened Coulomb interaction  $W - v$ .
- **echo 2|hsfp0\_sc** : gives the correlated part of the self-energy.
- **echo 0|hqpe\_sc**: gather data and write down final results into **sigm**, **QPU**, **TOTE.UP** files.

## 6.4 Other functions (or scripts)

In addition to **gw\_lmfh**, there are some other additional scripts and functions.

- **gw\_lmfh** : The one-shot  $GW$  calculation. Lifetime(impact ionization rate) of QPs.
- **gwsc** : QSGW calculation explained here
- **epsPP\_lmfh**, **eps\_lmfh** : Dielectric function without or with local-field effects.
- run-mode 4 of **hsfp0**: to plot the spectrum function  $\Sigma(\omega)$ . (need to be fixed again probably).
- **epsPP\_lmfh\_chipm** : non-interacting spin susceptibility. One-degree of freedom like Rigid moment approx. After it ends, you need to do **calj\_nlfc\_metal** and/or **calj\_summary\_mat** to get the full spin susceptibility.
- **genMLWF** : Wannier function and its matrix elements of the Screened Coulomb interaction.

---

<sup>12</sup>Correlation part due to cores is neglected. In future, we will switch to a version without PB for core part to reduce computational time and for numerical accuracy.

## 7 Cautions for usage

1. == not meaningful total energy in QSGW==

Total energy shown in QSGW mode in current version is not meaningful. (just treat as an indicator to convergence).

2. == Do we use VWN or GGA for QSGW? ==

In principle, QSGW results should not depends on VWN or GGA (XCFUN=1 or 103 in ctrl). But there is minor dependence, because

1. frozen core density.
2. core eigenfunctions.
3. radial basis functions
4. Slight numerical reason

(This is probably because Sigma-interpolation procedure But not exactly figured out yet → affect about 0.02eV as for band gap for GaAs. ). In anyway, use VWN (HAM\_XCFUN=1) as standard. And such technical things affects, 0.05 eV level of error for band gap.

3. EH and EH2 : For si, if EH and EH2 are the same, the following error occurred.

```
fexit,fexit2,fexit3 error retval=      -1
Exit -1 zhev_tk2: nev /=nevx something wrong.
```

The large EH, EH2 get to be meaningless. We usually use up to  $\sim 2$ . (If you use very large EH such as  $E \sim 10$ , I am not so sure weather it is )

4. The options about the product basis within MT. (SeungWoo's memo)

```
<PRODUCT_BASIS>
tolerance to remove products due to poor linear-independency
0.100000D-02 ! =tolopt
```

When the product basis are made, we may have poorly linear independent basis. For example, one in the set  $\{f_1, f_2, \dots, f_n\}$  would be almost give by a linear-combination of others. We need to make the linear-independent set. Therefore, after calculating the overlap matrix  $\langle f_i | f_j \rangle$ . We do diagonalization, then we remove eigenvectors corresponding to small eigenvalues than `tolopt`. See the **hbasfp0** command in **gwsc**

```
lcutmx(atom) = maximum l-cutoff for the product basis.
4 4 4 2 2 4 4
```

For  $\phi_1 \times \phi_2$  case,  $|l_1 - l_2| \leq l_{tot} \leq |l_1 + l_2|$ . So 'lcutmx' changes the maximum cutoff for the  $l_{tot}$ . The order is the same as the order of atoms in the **ctrl** file.

```
atom  l  nnvv  nnc !
1     0    3    3
1     1    3    2
1     2    2    1
```

'atom' means the atom number identified in the **ctrl** file.

'l' is the angular momentum quantum number.

'nnvv' is the number of radial functions (valence) on the augmentation-waves.

'nnc' is the number of radial functions for core.

The latter two ones, 'nnvv' and 'nnc', will be understood more clearly if you see the following ones.

atom	l	n	occ	unocc	! Valence(1=yes,0=no)
1	0	1	1	1	! 5S_p -----
1	0	2	0	0	! 5S_d
1	0	3	1	1	! 4S_l
1	1	1	1	1	! 5p_p
1	1	2	0	0	! 5p_d
1	1	3	1	1	! 4p_l

Above options are about the product basis set within MT (Valence).

‘atom’ and ‘l’ are explained above. ‘nnvv’ for ‘atom = 1 and l = 0’ was ‘3’ so this case we have 3 basis (‘n = 1, 2, 3’)

‘n’ is the degree of freedom of the radial function,  $\phi$ . ‘n = 1’ means  $\phi$ , ‘n = 2’ means  $\dot{\phi}$ , and ‘n = 3’ means kind of  $\ddot{\phi}$ , which the dot above the letter represents the differentiation with respect to the energy. So ‘n = 1 and 2’ is related to the linearization of the radial function and ‘n = 3’ is the local orbital which is restricted in MT. The local orbital can be modified changing ‘PZ’ in the **ctrl** file. Finally, the number of the basis set which is needed for expanding eigenfunctions is  $(l+1)^2 \times n$ .

‘occ’ and ‘unocc’ mean that we use only ones that checked as ‘1’, in other words we neglects ‘0’ cases for making product basis. Be careful for confusion with name ‘occ’ and ‘unocc’. These don’t mean that occupied or unocc. When making product basis,  $M = \phi_1 \times \phi_2$ , ‘occ’ corresponds to  $\phi_1$  and ‘unocc’ to  $\phi_2$ . For example,

atom	l	n	occ	unocc	! Valence(1=yes,0=no)
1	0	1	1	1	! 5S_p -----
2	3	1	0	1	! 4f_p

If the options are like the above, the product basis will be consists of  $(\phi_1 = \phi_{atom=1,l=0}) \times (\phi_2 = \phi_{atom=1,l=0})$ ,  $(\phi_{atom=1,l=0} \times \phi_{atom=2,l=3})$ . As you can see,  $(\phi_1 = \phi_{atom=2,l=3})$  is skipped.

In the **ctrl** file, ‘EH’ controls the l part. As for ‘EH’, (s, p, d, f) are used but **GWinput** file uses (s, p, d, f, g). ‘EH’: HEAD part. ‘GWinput’: contains TAIL part... need more explanation.

atom	l	n	occ	unocc	ForX0	ForSxc	! Core (1=yes, 0=no)
1	0	1	0	0	0	0	! 1S -----
1	0	2	0	0	0	0	! 2S
1	0	3	0	0	0	0	! 3S

Above options are about the product basis set within MT (Core).

‘nnc’ for ‘atom = 1 and l = 0’ was ‘3’ so this case we have 3 basis (‘n = 1, 2, 3’)

Finally, for the convergence check, we can modify the following three things, (i) tolerance, (ii) lcutmx, and (iii) occ and unoccu.

== one show QSGW (not one-shot GW) ==

one-shot QSGW can be useful in cases.

As it contains off-diagonal part, we can resolve band tanglement problem in Ge (no band gap).

== Restart calculation in lda ==

lmf(lmf-MPIK) read rst.\* in default.  
 rst contains electron density.  
 If rst is already converged, it stops after two iteration.  
 rst contains atomic positions.  
 So, in order to read atomic positions change in ctrl,  
 Use options shown in lmf --help.

== Restart calculation in qsgw ==  
 To remove mixsigm\* (mixing for sigm), maybe required.

== iteration check ==  
 First, watch console output of gwsc (do redirect to output file)  
 Need to check OK! signs arrayed on 1st columns.

gwsc iteration is time consuming,  
 So we need to check calculations are normally going on or not.

Memory inefficiency.  
 Set 'KeepEigen off' and 'KeepPPOVL' off.  
 In fact, our code is still inefficient for memory usage.

grep gap llmf ---> minimum gap at mesh point.  
 see save.\* , or grep '[xc]' save.\*  
 the end of iteration of lmf is shown as x or c.  
 (if failed, QPU file.  
 dqpu QPU.4run QPU.3run  
 As for usual semi-conductor, accuracy about 0.1 eV is limit of current implementation.  
 Set vwn (xcfun=1) looks better (stable) for GW.

\$grep rms lqpe\*  
 shows  
 ... rmsdel=2.44D-04  
 ... rmsdel=4.91D-03  
 ... rmsdel=2.44D-04  
 ... rmsdel=3.37D-04

If rmsdel is getting to be smaller, it is on convergence path.  
 (but in magnetic cases, it may give be too good even not yet going to  
 be converged..., because magnetic energy is so small)

grep diffe llmf ---> difference of energies of each iteration.

ehf (harris energy)  
 ehk (Hohenberg kohn energy)

== emax cutoff for APWs. ==  
 We can not use so many APWs in current version,  
 because of overcompleteness (this is because null vector within MTs),  
 In anyway, use pwemax=3 as standard (test it with 4 or 5).

To avoid failure of calculation, we may use smaller MT radius for alkali, and alkali-earth elements.

In feature, I think we can introduce pseudopotentials for these atoms only.

== Check Used MTO

Near beginig of console output, what MTO you use is shown as: (GaAs case).

sugcut: make orbital-dependent reciprocal vector cutoffs for tol= 1.00E-06

spec	l	rsm	eh	gmax	last term	cutoff
Ga	0*	1.13	-1.00	6.579	1.19E-06	1459
Ga	1*	1.13	-1.00	7.028	1.26E-06	1807
Ga	2*	1.13	-1.00	7.475	1.09E-06	2109
Ga	3	1.13	-1.00	7.920	1.06E-06	2637
Ga	0*	1.13	-2.00	6.579	1.19E-06	1459
Ga	1*	1.13	-2.00	7.028	1.26E-06	1807
Ga	2	1.13	-2.00	7.475	1.09E-06	2109
As	0*	1.18	-1.00	6.300	2.13E-06	1243
As	1*	1.18	-1.00	6.720	1.26E-06	1471
As	2*	1.18	-1.00	7.140	1.37E-06	1837
As	3	1.18	-1.00	7.558	1.05E-06	2229
As	0*	1.18	-2.00	6.300	2.13E-06	1243
As	1*	1.18	-2.00	6.720	1.26E-06	1471
As	2	1.18	-2.00	7.140	1.37E-06	1837

== gwsc cause error stop.

Have you ever changed MTO setting? Consistent with GWinput?

== QSGW for Fe.

It is better to use 3p as core. Furthermore, 3d+4d as valence is better.

Thus we need to set PZ=0,3.9,4.5

I also got aware that emax\_sigm should be large enough ( $4\epsilon_{\text{sim}} 5 \text{ Ry}$ )

to have smooth band dispersion. n1n2n3 can be 10x10x10.

== RSRNGE: enlarge RSRNGE ===

Use RSRNGE=10 or so (in cases, RARNGE=20 or more is required),

for large number of k points. Try and enlarge it if it fails with a

message "Exit -1 rdsigm: Bloch sum deviates more than allowed tolerance (tol=5e-6)".

We will have to make it automatic in future.

== QOP check

In cases, it is better to use QOPchoice=2 instead of default QOPchoice=1.

(For slabs, QOPchoice=2 may be better; need check more. In anyway,

it is problematic to use unbalanced k points for anisotropic cell).

See Copmuter Physics Comm. 176(2007)1-13).

=== When calculation in LDA level fails ===

when calculation fails in LDA level.

(1) smaller MT

(2) fewer PW. smaller pwemax.

(3) core as semicore.

=== LDA+U ===  
not yet written...

=== MAE by rotating crystal ===  
(we have a sample at lm7K/TESTsmamples/MAEtest/, but only in GGA/LDA).

=== spin wave ===  
J calculation.

====  
If not stable convergence in gwsc, try to set  
mixbeta 0.5  
(and/or mixpriorit 3 or something)  
at the begining of sigma.

=====  
cleargw (directory):  
This command clean up up intermediate files under (directory).  
This recursively into deeper level. Be careful, or edit it.  
I use it as '>cleargw .'.

-----  
Magnetic moment within MTs are shown as  
-----

charges:		old	new	
smooth		17.240314	17.240740	...
mmom		0.000024	-0.000010	
site	1	6.207135	6.206590	
mmom		1.062276	1.062991	<--- here
site	2	6.207115	6.206834	
mmom		-1.062323	-1.062958	<--- here
site	3	1.172718	1.172918	
mmom		0.000011	-0.000011	
site	4	1.172718	1.172918	
mmom		0.000011	-0.000011	

In this case, MTsite1 has 1.062991 and MTsite2 has -1.062958.

>grep 'lin mix' -A30 llmf

can take out this message (if console output is in llmf).

-----

ORBITAL MOMENT in pertubation:

-----

Try

```
>lmf nio --rs=1,0 -vso=1 --quit=band >llmf
```

After converged, try

```
>grep IORBTM -A20 llmf
```

Then llmf shows orbital moment in first order perturbation.

(Here --rs=1,0 read rst.\* file but not change it. See >lmf --help.

--quit=band means quit just after band calculation.)

== EPS mode,

Check Im part of chi0 is smoothly damping at high energy (typically 1Ry or larger energy range). If there is some large Im part remains, something strange (usually due to orthogonality problem of eigenfunctions when you set low q).

Related source codes are in ecalj/lm7K/ .

A command ecalj/lm7K/ctrlgenM1.py can generate 'standard input file (ctrl file)' just from a given crystal structure file called as ctrls file.

Binaries are lmf and lmf-MPIK (MPI k-parallel version).

## 7.1 lmf -help

lmf -help show option of -rs=(five numbers); this let lmf know how to read atm.\* file which is the initial atom file by lmfa.

## 8 Wannier function

xxxxxxxxxx under construction xxxxxxxxxxxxxxxxxxxxx

(See also ecalj/fpgw/Wannier/README)...

We can generate Wannier functions (maximally localized Wannier Functions or similar) by a script **genMLWF**. Run examples in ecalj/fpgw/MATERIALS/\*MLWF. To run the script, we need to set options in GWinput. For initial condition, we need

<MLWF>

```
5          # gaussian, nwf
```

```
1 1 1 1 1 # nphi(1:nwf)
```

```
9 14 2.0 1.0 phi,phidot and lamda(angs) of gaussian 1, #iphi(j,i),iphidot(j,i),r0g(j,i),wphi(j,i)
```

```
10 15 2.0 1.0 phi,phidot and lamda(angs) of gaussian 2
```

```
11 16 2.0 1.0 phi,phidot and lamda(angs) of gaussian 3
```

```
12 17 2.0 1.0 phi,phidot and lamda(angs) of gaussian 3
```

```
13 18 2.0 1.0 phi,phidot and lamda(angs) of gaussian 3
```

</MLWF>

In addition, we have some settings (energy windows and so on). This is the example of the initial conditions for Cu case. 5 is the number of Wannier function. The most left one means  $\phi$  index and the right one of it is  $\dot{\phi}$  index. They are written in the @MNLA\_CPHI file.

Then we can run **genMLWF**. After it finished, we can analyze it results. (if you don't need Wannier function plot, You can skip a line of wanplot in genMLWF. Then we don't need

to set `vis_wan_*` options.)

## 8.1 lwmatK1 and lwmatK2

If you input the following command

```
>grep Wan lwmatK*
```

You will get the following results. (This case : Cu cases)

```
lwmatK1: Wannier    1    1  24.644475    0.000000 eV
lwmatK1: Wannier    1    2  24.644576    0.000000 eV
lwmatK1: Wannier    1    3  25.471361    0.000000 eV
lwmatK1: Wannier    1    4  24.644575    0.000000 eV
lwmatK1: Wannier    1    5  25.470946    0.000000 eV
lwmatK2: Wannier    1    1   0.000000 eV  -21.263759  -0.000000 eV
lwmatK2: Wannier    1    2   0.000000 eV  -21.263839   0.000000 eV
lwmatK2: Wannier    1    3   0.000000 eV  -21.931033  -0.000000 eV
lwmatK2: Wannier    1    4   0.000000 eV  -21.263839  -0.000000 eV
lwmatK2: Wannier    1    5   0.000000 eV  -21.930702  -0.000000 eV
```

### Wannier Branch now under developing (imported from T.Miyake's Wannier and H.Kino's).

A. make at `ecalj/fpgw/Wannier/` directory, and do make, and make install.

(need to check Makefile first). You first have to install `fpgw/exec/` in advance.

B. Samples are at these directories.

`MATERIALS/CuMLWFs` (small samples),

`MATERIALS/CuMLWF/`

`MATERIALS/CuMLWFs/`

`MATERIALS/FeMLWF/`

`MATERIALS/NiOMLWF/`

`MATERIALS/SrVO3MLWF/`

C. With `GWinput` and `ctrl.*`, run

```
>genMLWF
```

at these directories.

In `GWinput`, we supply settings to generate Wannier functions. (Sorry, not documented yet..)

D. After `genMLWF`, do

```
>grep Wan lwmatK*
```

then compare these with `Result.grepWanlwmatK`

These are onsite effective interactions (diagonal part only shown).

`*.xsf` are for plotting the Maximally localized Wannier functions.

Anyway, documentation on Wannier is on the way half.

Time consuming part (and also the advantage) is for effective interaction in RPA.

Look into the shell script `genMLWF`; you can skip last part if you don't need the effective interaction.

## 9 ctrl file details

A `ctrl` file is usually generated from a `ctrls` file by the `ctrlgenM1.py` (a crystal structure file is not "`ctrl`" but "`ctrls`"). It contains self explanation. Here we give complementary explanations to it. Let us look into a `ctrl` file. This is a head part of `ctrl.cu` generated by `ctrlgenM1.py`:

```

### This is generated by ctrlgenM1.py from ctrls
### For tokens, See http://titus.phy.qub.ac.uk/packages/LMTO/tokens.html.
### Do lmf --input to see all effective category and token ###
### It will be not so difficult to edit ctrlge.py for your purpose ###
VERS    LM=7 FP=7          # version check. Fixed.
IO      SHOW=T VERBOS=35 TIM=2,2
        # SHOW=T shows readin data (and default setting at the begining of
        console output)
        # It is useful to check ctrl is read in correctly or not
        (equivalent with --show option).
        # larger VERBOSE gives more detailed console output.
SYMGRP find # 'find' evaluate space-group symmetry automatically.
        # Usually 'find is OK', but lmf may use lower symmetry
...

```

Note that # means comment lines. We can also use lines starting from % const ... to define variables and set constant.

We see “categories” such as **VERS**, **IO**, and so on. The beginning of categories are starting from the first column. Under categories, we have “tokens” such as **VERBOSE**. Thus we specify full name of token **VERBOSE** under category **IO** as **IO\_VERBOSE**.

- **IO\_TIM** is for debugging. It shows which subroutines are called and so on. Bigger number shows deeper subroutines.
- **SYMGRP** is a category without token under it; we set generators of space group (See explanation in previous paragraph). When we set **find**, it automatically calculate symmetry of crystal lattice. If we like to enforce symmetry, set some of generators which are shown by **lmchk**.
- We see **ctrls** is embedded in the **ctrl** by **ctrlgenM1.py**.

```

... (skip) ...
% const  da=0 alat=6.798
STRUC    ALAT={alat} DALAT={da}
        PLAT=  0.0 0.5 0.5  0.5 0.0 0.5   0.5 0.5 0.0
        NL=4 NBAS= 1  NSPEC=1
SITE     ATOM=Cu POS=0 0 0
... (skip) ...

```

**NL**, **NBAS**(number of **SITE**) and **NSPEC**(number of **SPEC**) are automatically added by **ctrlgenM1.py**. It is possible to deform unit cell by adding optional tokens (it is possible to rotate **PLAT** for magnetic anisotropy calculation). See <http://titus.phy.qub.ac.uk/packages/LMTO/tokens.h>. For new calculations, it is better to find some examples first.

- **SITE** category: As for MT sites, we have two categories. (1)**SPEC**(species) and (2)**SITE**(specify centers of atoms(species) in primitive cell). As for **SPEC**, we specify MTs(radius, Z, MTOs on it) appeared in the cell. These are defined subtokens under **SPEC\_ATOM=foobar** (we have multiple **SPEC\_ATOM=foobar**).

Then we place these MTs at **SITE** sections in the cell. At **SITE**, we specify atomic sites (What **SPEC\_ATOM** is placed to positions by **POS**) in a primitive cell. We set **POS=** by direct form (Cartesian) but with the unit of **ALAT+DLAT**. Total number of **SITE** (number of tokens **SITE\_ATOM**) is the number of atoms in the primitive cell. Setting **POS=** under **SITE\_ATOM=foobar** means that we place MT named as **foobar** defined in

SPEC\_ATOM=foobar. In addition, we can set SITE\_ATOM\_RELAX, if you like to find relaxed structure (we simultaneously set DYN category) in LDA. As for relaxation, see `LaGa0_relax/ctrl.lagao` example, and read <http://titus.phy.qub.ac.uk/packages/LMT0/tokens.html#DYNcat>.

The SITE\_ATOM=foobar (with same foobar with different POS) are not necessarily equivalent with respect to the space group operation of a system. Thus SITE\_ATOM=foobar are divided into “classes” which are connected by the operation. The lmf automatically judge “classes” (see also info by lmchk). Thus not need to specify it, but it may be better to check it. A sample is `lmchk lagao` at `~/ecalj/lm7K/TESTsamples/LaGa0_relax`

- **SPEC** category: In ctrls, we have not yet specified contents of SPEC; we have just given default symbols or only Z= when we use non-default names (shown by `ctrlgenM1.py` – `showatomlist`). The command `ctrlgenM1.py` adds default SPEC sections.

We have some SPEC\_ATOM, under which we give subtokens such as SPEC\_ATOM\_R(MT radius), SPEC\_ATOM\_Z(nucleus charge), cutoff parameters of angular momentum, and so on. These SPEC\_ATOM is refereed to in SITE.

An example of SPEC category is

SPEC

```
ATOM=Fe Z=26 R=1.70
  KMXA={kmtx} LMX=3 LMXA=4 NMCORE=1
  PZ=0,3.9,4.5
  EH=-1 -1 -1 -1 RSMH=0.85 0.85 0.85 0.85
  EH2=-2 -2 -2 RSMH2=0.85 0.85 0.85
  MMOM=0 0 2 0
```

ATOM=... (then the similar block of ATOM= are repeated.)

...

Under the token ATOM=Fe, we have subtokens SPEC\_ATOM\_Z, SPEC\_ATOM\_R, and so on.

Subtokens Z= is the nucleus charge and R= MT radius. Note that Fe is just a name to distinguish MT sphere in the cell. If you set SPEC\_ATOM\_Z=27, it is recognized as Co (since Z=27). LMX=3 is the maximum l of MTOs. Thus maximum l of MTO is l=3. The maximum of l to expand electron density and potential within MT is LMXA (in contrast to usual LAPW), we can use quite small LMXA such as LMXA=4. NMCORE=1 means we calculate core density without non magnetically-polarization. This can reduce computational confusion.

PZ is to set local orbital (if not, no local orbitals). EH and RSMH are to specify first set of MTOs. (We can check how local orbitals are set by lmfa explained in the next section). EH2 and RSMH2 are to specify second set of MTOs.

After PZ=, we have three numbers. These are numbers for s,p,d,f,g,... channels. Zero means not exist. You can use space or comma(,) as delimiter. Here not only the integer part of principle quantum number, but also the fractional part should be supplied (If PZ=0,3,4, it does not work.) Now PZ=3.9 for p and PZ=4.5 for d. This means we use local orbital for 3p, and local orbital for 4d (fractional parts (continuous principle quantum number) are large  $\sim 0.9$  for core like orbital, and smaller

for extended orbital  $\sim 0.3$  or something. See Logarithmic Derivative Parameters at <http://titus.phy.qub.ac.uk/packages/LMT0/lmto.html>). This is a little confusing, thus we will explain this in appendix. See Sec.??.

EH(damping factor), and RSMH (where the smooth Hankel function bent) determines MTOs (or its envelope function as a smooth Hankel function). We now set four numbers for them. Thus we set MTOs s,p,d,f with EH=-1 and RSMH=0.85. Our current test shows that RSMH is one half of R (that is,  $0.85=1.70/2$ , but minimum RSMH is 0.5) and not need to be dependent on s,p,d,f. (If LMX=2, s,p,d are allowed and no f MTOs.) EH is -1; not need to change except test purpose. In a similar manner, EH2 and RSMH2 for second set of MTOs are given. Just three numbers means these for s,p,d.

MMOM=s,p,d,f... gives initial condition of magnetic moment in  $\mu_B$  (number of up-down electron).

In cases such as As, the local orbital given by default ctrl is responsible of rather deep core, and it is not need to be treated as valence electrons. In such a case, we don't need local orbital.

In the case of AntiFerro-II NiO, it contains two NiO in a primitive cell. Thus it is reasonable to have two SPEC\_ATOM as Ni1 and Ni2, although subtokens under ATOM=Ni1 and ATOM=Ni2 (e.g. SPEC\_ATOM\_EH for them) are the same except initial condition of magnetic moment of MMOM=s,p,d,f... See example of NiO.

The minimum help of call Category\_token\_subtoken are listed with minimum explanation with

```
$ lmf --input
```

It gives a long output. But many of them are experimental and not need to manage them. A part of it is

Token	Input	cast	(size,min)
-----			
...	...		
STRUC_ALAT	reqd	r8	1, 1
Scaling of lattice vectors, in a.u.			
...	...		

This is an minimum explanation of it. "reqd" means "required" (no default). r8 means it read with real number, 1,1 means that ALAT=xxx should contain one number minimum (max is also one) (See also STRUC\_PLAT, and so on).

There are kinds of examples in ecalj packages. Please look into their ctrls.\* and ctrl.\* These are in lm7K/TESTsample/\* and ecalj/CMDsamples. In addition, ecalj/MATERIALS contain many samples (need a command); see a later subsection.

As for what is shown in \$ lmf --input, most of important tokens are already described in the ctrl file generated by ctrlgenM1.py. So, we don't need to care many options shown by it.

But we have not yet explained some useful features; STRUC category to deform crystal; DYN category for dynamics; LDA+U treatment; Adding background charge; Core-Hole treatments. We will prepare examples for it if requested.

<http://titus.phy.qub.ac.uk/packages/LMTO/tokens.html#STRUCcat>  
<http://titus.phy.qub.ac.uk/packages/LMTO/tokens.html#DYNcat>

For QSGW calculation:

We need a setting in ctrl file to read sigm file (HAM-SIGP). It is simplified now, and not need to care it so much. As we set RDSIG=12 in defaults, lmf read sigm file and add it to one-body potential as long as sigm.\* exist.

**NOTE for old users:** We now set SIGP[MODE=3 EMAX=9999.] in ctrl file to read self-energy in lmf (or lmf-MPIK). This is because we use very localized MTOs (similar with the Maxloc Wannier). Our test shows reasonable results and this simplify algorithms. In my previous version, we asked you to use SIGP[MODE=3 EMAX=2.0] where EMAX is a little (0.5Ry) less than `emax_sigm`. If something strange occurs, try this setting).

- In principle, QSGW result should not depended on the choice of XCFUN. However, it can affect slightly. In our tests, it seems slightly better to use VWN (XCFUN=1) for QSGW calculations. (BUT need to check more...)

## 9.1 How to set local orbitals

As we stated, do "lmfa |grep conf" to check used MTO basis.

We have to set SPEC\_ATOM\_PZ=?,?,?

(they ordered as PZ=s,p,d,f,... ) to set local orbitals.

lmv7 (originally due to ASA in Stuttgart) uses a special terminology "continious principle quantum number for each l", which is just relatated to the logalismic derivative of radial funcitons at MT boundary. It is defined as

$P = \text{principleQuantumNumber} + 0.5 - 1/\pi * \text{atan}(r * 1/\phi \text{ d}\phi/\text{dr})$ ,

where  $\phi$  is the radial function for each l. For example,

$P = n.5$  for  $l=0$  of free electron (flat potential) because  $\phi=r^0$ ,

$P = n.25$  for  $l=1$  because  $\phi=r^1$ ;

$P = n.147584$  for  $l=2$  because  $\phi=r^2$ ;  $P = n.102416$   $n.077979$  for  $l=3,4$ .

(Integer part can be changed). See Logarithmic Derivative Parameters in <http://titus.phy.qub.ac.uk/packages/LMTO/lmto.html#section2>

Its fractioanl part  $0.5 - \text{atan}(1/\phi \text{ d}\phi/\text{dr})$  is closer to unity for core like orbital, but closer to zero for extended orbitals.

Examples of choice:

Ga p: in this case, choice 0 or choice 2 is recommended.

We usually use lo for semi-core, or virtually unoccupied level.

(0)no lo (4p as valence is default treatment without lo.)

3p core, 4p valence, no lo: default.

Then we have choice that lo is set to be for 3p,4p,5p.

(1)3p lo ---> 4p val (when 3p is treated as valence)

3d semi core, 4d valence

```

Set PZ=0,3.9
(P is not required to set. *.9 for core like state. It is just an initial condition.)
(2)5p lo ---> 4p val (PZ>P)
Set PZ=0,5.5
5.5 is just simply given by a guess (no method have yet
implemented for
    If 5.2 or something, it may fails
    because of poorness in linear-dependency. We may need to observe
    results should not change so much on the value of PZ.

(3xxx)4p lo ---> 5p val (we don't use this usually. this is for test purpose)
4p lo, 5p valence
Set PZ=0,4.5 P=0,5.5 (In this case, set P= simultaneously).
(NOTE: zero for s channel is to use default numbers for s)

Ga d: (in this case, choice 0 or choice 1 is recommended).
(0)no lo (3d core, 4d valence, no lo: default.)
    Then we have choice that lo is set to be for 3d,4d,5d.
(1) 3d lo ---> 4d val (when 3d is treated as valence)
    Set PZ=0,0,3.9 (P is not required to set)
(2) 5d lo ---> 4d val (PZ>P)
    Set PZ=0,0,5.5
(3xxx) 4d lo ---> 5d val (this is for test purpose)
    Set PZ=0,0,5.5 P=0,0,4.5
    (NOTE: zero for s,p are to use default numbers )

If you like to read from atm.ga file instead of rst file(if exist).
You have to do lmf --rs=1,1,0,0,1, for example. See lmf --help
Because rst file keeps the setting of MTO, thus change in ctrl is not
reflected without the above option to lmf.
=====

```

## 10 GWinput details

### 10.1 generate a template of GWinput

As in the previous section, we need two input files `ctrl.si` and `GWinput`. In principle, these two determines final results uniquely. A template `GWinput.tmp` is generated by `mkGWIN_lmf2`. Required files are

#### Input files

- `ctrl.si` : The control file for PMT method.

(Recently modified `mkGWIN_lmf2` runs `lmfa` internally. If you use older version, do `lmfa` in advance).

#### Output files

- `GWinput.tmp` : A file including computational conditions for the *GW* calculation. In addition, it specifies the **k** points for which you calculate the QP energy.

When you run `mkGWIN_lmf`, it asks you to supply three numbers for BZ integration as  
== Type three integers n1 n2 n3 for Brillouin Zone meshing for GW! ==  
n1=

Then you need to type a number e.g. as "2"  for n1. Then you need to repeat it for n2 and n3 as

n1= 2

n2= 2

n3= 2

. These numbers specifies what **k** points in BZ is used for BZ integration (In this case,  $2 \times 2 \times 2 = 8$  **k** point in the 1st BZ is used. Roughly speaking, we need  $4 \times 4 \times 4$  (or  $6 \times 6 \times 6$ ) to get band gap for Si and so on, with  $\approx 0.1$  eV accuracy.)

Then you have to edit `GWinput.tmp` and copy it to `GWinput`. We details the `GWinput` in later chapter.

We need to repeat `mkGWIN_lmf2` when you change MTO sections in `ctrl` file (adding PZ case, and so on).

### 10.2 overview of GWinput

(Because of historical reason, input file is different from `ctrl.*`).

The main input files is `GWinput`. This controls the setting of *GW* calculation. The file `GWinput` consists of structures as

*keyword1 data1*

*keyword2 data2*

...

In each lines, it consists of keyword and data. Data can be single or plural. As for keywords, upper case or Lowercase is not distinguished. All keywords should start from 1st column (no space at head). Order of lines are irrelevant. As for logical variable, you can use anything "true, yes, on, 1, T" for .true., and anything "false, no, off, 0, F" for .false.

Or we have "tag sections" in `GWinput` specified by `<PRODUCT_BASIS>`, `<QPNT>`, `<PBASMAX>`, `<QforEPS>`, and `<QforEPSL>`. (`<PRODUCT_BASIS>` is requires for all kinds of calculations. `<PBASMAX>` is optional. `<QforEPS>` and/or `<QforEPSL>` are required for epsilon mode). It is like

`<PRODUCT_BASIS>`

tolerance to remove products

```

0.100000D-02 ! =tolopt
lcutmx(atom)
3 3
atom 1
...
</PRODUCT_BASIS>

```

. In these tag sections, you have to keep format for its own (usually numbers are read by free format `read(*,*)`).

The fundamental readin routine for GWinput is a subroutine `getkeyvalue` defined in `gwsrc/keyvalue.F`. `getkeyvalue` is a general and convenient readin routine in full use of the f90 features. Read a head part of the file and try to do "grep getkeyvalue \*.F" in `gwsrc/` or `main/` so as to see how to use it (test routine is `main/kino_input_test.F`.)

So the GWinput consists of three sections

1. General section
2. <PRODUCT\_BASIS> section
3. <QforEPS>, <QforEPSL> section (only effective for dielectric function mode)
4. <QPNT> section (only effective for one-shot mode)
5. <PBASMAX> section (optional)

We will explain each by each in the followings.

### 10.3 General section

In general section, it looks like

```
! ##### From GWINO #####
n1n2n3      1      1      1 ! for BZ meshing in GW
QpGcut_psi   4.000 !(See unit_2pioa for unit) |q+G| cutoff for eigenfunction.
QpGcut_cou   3.000 !(See unit_2pioa for unit) |q+G| cutoff for Coulomb and W.
unit_2pioa off ! off --> a.u.; on--> unit of QpGcut_* are in 2*pi/alat
alpha_OffG   1.000 !(a.u.) Used in auxially function in the offset-Gamma method.
!emax_chi0   99999.000 !(Ry) emax cutoff for chi0 (Optional)
emax_sigm    3.000 !(Ry) emax cutoff for Sigma

! ##### FREQUENCIES from GWIN_V2 #####
dw           0.005000 !(a.u.) energy-mesh (bin width size) along real axis.
omg_c        0.040 !(a.u.) energy-mesh is twiced at omg_c
! coarser mesh for higher energy. Width get to be doubled at omg_c.
iSigMode     3 ! QSGW mode switch for gwsc. use =3.
niw          10 ! Number of frequencies along Im axis. Used for integration to get Sigma_c
! E.g. try niw=6 and niw=12
delta        -0.10D-05 !(a.u.) Broadening of x0. negative means tetrahedron method.
! used by hx0fp0. You get smeard x0 with abs(delta).
deltaw       0.020000 !(a.u.) Mesh for numerical derivative to get the Z factor
esmr         0.003000 !(Ry) used by hsfp0. Keep esmr smaller than band gap for insulators
! Poles of G^LDA are treated as if they have width esmr in hsfp0.
! Change esmr for metals. See DOSACC*---especailly around Ef.
GaussSmear on ! Gaussian or Rectangular smearing for Pole of G^LDA with esmr for hsfp0.
```

#### 1. BZ integration.

**n1n2n3** 3 integers as  $N_1, N_2, N_3$  (no default); They are  $\geq 0$ .

Brillouin Zone mesh for integration is determined by keywords **BZmesh** and **n1n2n3**. Current version only allow regular mesh point including Gamma point for  $G \times W$ . But not that **Chi\_RegQbz** below allow you to use off-Gamma mesh for  $W(\omega)$  (and dielectric function mode).

We usually take '4 4 4', '6 6 6' or '8 8 8' for GaAs. For metal such as Fe, '10 10 10' or more is better.

**Chi\_RegQbz** (on or off)

**Chi\_RegQbz** = on (default): Use regular mesh (including gamma) for eps calculation.

**Chi\_RegQbz** = off : Use off-Gamma mesh (Not including gamma) for eps calculation.

(In cases, **Chi\_RegQbz** off gives faster convergence as for **n1n2n3**; not only for GW, but also for dielectric functions **eps\_lmfh**.)

#### 2. Plane wave ( $\mathbf{q} + \mathbf{G}$ ) cutoff

**QpGcut\_psi** 1 real (no default)

**QpGcut\_Cou** 1 real (no default)

**unit\_2pioa** 1 logical (no default)

We have two cutoff for  $\mathbf{q} + \mathbf{G}$ . **QpGcut\_psi** is the cutoff of  $|q + G|$  for the IPW in the expansion of the eigenfunctions. **QpGcut\_Cou** is for the IPW of the interactions  $v, D, W$ .

Its unit is specified by `unit_2pioa` ; "off" means unit in a.u. and "on" means in unit of  $\frac{2\pi}{\text{alat}}$ . (alat is length scale unit in ctrl.\*).

Rule of thumb: `QGcut_psi` is a little (usually 0.5 or so) larger than `QpGcut_cou`. It becomes accurate if we use large `QpGcut_cou`. But it enlarge size of IPW(interstitial plane wave) part of Mixed product basis. For test, try 2.7, 3.2, 3.7 for `QGcut_cou` (and add 0.5 or 1 for `QGcut_psi`). Larger one is expensive.

We expand eigenfunctions in the Muffin-tin division of the space. See Eq.[?] in Ref.[?]; in the current *GW* implementation, we use very simple form of eigenfuncitons (not by the 3-component formalism in the [?]).

Thus the form of expansion is just related to the division of space; not directly related to the difference among LAPW, LMTO, and PMT.

### 3. Eigenfunctions within MTs (no parameters setting for them).

The radial functions (phi and phidot for each  $l$ ), corresponding to the true parts, (= 2nd component in the 3-component formalism [?]), are automatically determined already in the one-body part of program **lmf-MPIK**.

### 4. Cutoff for used bands.

`emax_chi0`: 1 real (optional,default= $\infty$ ), in Ry

`emax_sigm`: 1 real (optional,default= $\infty$ ; We usually use 3 Ry).

`emax_sigm` is the maximum limit of the self-energy (measured from the Fermi energy). See the paper [?] which shows how the results are affected by `emax_sigm`. But in cases, small `emax_sigm` can give poor dispersion curve (slightly unnatural behavior) because of sudden cutoff by `emax_sigm`. However, we like to use smaller value to reduce computational time.

That is, larger is better, but expensive (And note that we simultaneously need to use empty spheres when we use large `emax_sigm`, as shown in [?], ).

Generally speaking, accuracy less than  $\sim 0.1\text{eV}$  (for bandgap) is allowance of current technique. Probably, it may be possible to have better accuracy, but it may ask us to repeat many calculations with changing conditions to confirm stability.

`nband_chi0`: 1 integer (optional,default= $\infty$ )

`nband_sigm`: 1 integer (optional,default= $\infty$ )

These specify how many bands you use in **hx0fp0** (for chi0) and in **hsfp0** (for sigma). Higher bands above them are neglected.

### 5. Energy mesh related parameters.

`dw`: 1 real (a.u.). Mesh width along real axis for  $W(\omega)$ .

`omg_c`: 1 real (a.u.).

`dw` and `omg_c` determines  $\omega$  mesh along real axis to calculate  $W(\omega)$ . In other words, `dw` and `omg_c` specify real space bins which we accumulate imaginary part weight of polarization functions. `dw` is bin width at  $\omega = 0$ , then bin width is twiced at `omg_c`. (Energy mesh is getting coarser at higher energy; in other words, the bin width is quadratically larger.) This choice of getting coarser is because we think  $W(\omega)$  around  $\omega \sim 0$  gives most important contribution to the GW approximation. If bins are too wide, dielectric function can be less accurate, but results are not necessarily so much affected. For metal, our code can capture Drude weight numerically. We do not need to be so sensitive to the choice of them usually.

(WARNING! Some of my examples may show as if they are in "(Ry)". But they are Wrong!)

**delta**: 1 real (a.u.). We usually use very small number as -1d-8 for gw\_lmfh, eps mode and so.

xxx does this really make the stabilization? xxx This is the size of  $\delta$  in denominator of  $\Pi$  (EQ.xxx). But (I think) we can (or can not) use it so as to make broadening for theoretical test (maybe not exactly corresponding to  $\delta$ ). or when you make calculation stabilized (Takao need to check this point again xxx!)

[Old note. Need check xxx: In gw\_lmf, it is used for broadening of  $x_0$  when it call hx0fp0. Then **delta** is  $\delta$  is EQ.32. The sign of **delta** is just used as a flag whether you use the tetrahedron method of dielectric constant [10] or not; minus sign means "Use the tetrahedron method for  $D$ "; plus sign means you do it by simple sum. You can usually use this default setting. But it might be possible to use a larger value to smear the fine structures on the energy-dependence of  $W$  in cases. This might be necessary if  $W$  is so energy-dependent and **dw** is not so small to resolve the structure —but I don't know.]

**niw**: 1 integer.

Number of integration points along the imaginary axis(FIG.1) to get  $\Sigma_c$ . See routines **wint\*** called from **sxcf\*.F**, which is called from the main routine **hsfp0.m.F** (or **hsfp0.sc.m.F** in the QSGW case). The integration points are  $i\omega'(n) = i(1/x(n) - 1)$ , where  $x(n)$  is the usual Gaussian-integration points for the interval  $[0,1]$ . In addition, we give the special analytical treatment for the peaky part at  $\omega' = 0$ . Out tests shows **niw**=6 for Si is good enough for 0.01 eV accuracy. The convergence as for **niw** is quite good. This integration scheme has been developed by Ferdi Aryasetiawan. The number of points should be the one of 6,10,12,16,20,24,32,40, or 48. It is because we use a subroutine **gauss** in **/gwsr/mate.F** prepared by Ferdi. We will replace better one in future. See II-F in Ref.I.

**GaussSmear**: 1 logical

**esmr**: 1 real (Ry). Used by hsfp0 (and hsfp0.sc for QSGW).

Poles of the Green function  $G^{\text{LDA}}$  are treated as if they have width **esmr** in hsfp0. If **GaussSmear** is on, each pole of  $G^{\text{LDA}}$  is smeared by a Gaussian function with  $\sigma = \text{esmr}$  in the calculation of hsfp0. If **GaussSmear** is off, we assume rectangular smearing for the poles. Usually it is necessary to take rather smaller value than band gap for insulators. Try to use 0.003 or so in the case of Si and **GaussSmear**=on.

For metal, this **esmr** is somehow related to how we capture the Fermi surface; In principle, we have to take the limit **n1n2n3**  $\rightarrow \infty$  and **esmr**  $\rightarrow 0$ ). However, we may inevitably use some finite **esmr** to make calculations converged.)

**deltaw**: 1 real (a.u.) only for one-shot case.

**deltaw** is the interval for the numerical derivative  $\frac{\partial \Sigma(\omega)}{\partial \omega}$  in EQ.8. We calculate  $\langle \psi^{\mathbf{k}n} | \Sigma(\epsilon^{\mathbf{k}n} + \text{deltaw}) | \psi^{\mathbf{k}n} \rangle$  and  $\langle \psi^{\mathbf{k}n} | \Sigma(\psi^{\mathbf{k}n} - \text{deltaw}) | \psi^{\mathbf{k}n} \rangle$  in addition to  $\langle \psi^{\mathbf{k}n} | \Sigma(\epsilon^{\mathbf{k}n}) | \psi^{\mathbf{k}n} \rangle$ . From these values, we can calculate two  $Z$  (or second-derivative of  $\Sigma(\omega)$ ), as shown in SECU. It will help to see whether the used **deltaw** is O.K. or not.

#### 6. Offset-gamma point.

**QOPChoice 0**: 1 integer

**QOP.Choice** gives how to determine the offset gamma points. Initially we take them as

1: —q— is ten times smaller than regular mesh.(default)

2: —q— is average in the Gamma cell (cell of BZ including Gamma point).

Then we choose only inequivalent **q** points based on the point group symmetry. Obtained offset gamma points is given in QOP file.

**alpha\_offG**: 1 real (a.u.)

**alpha\_offG** corresponds to  $\alpha$  in EQ.48. **alpha\_offG=1d0** is usually good in the sense that it seems to be almost a limit at  $\alpha \rightarrow 0$ . So you can usually fix it as **alpha\_offG=1d0**, and check the convergence as for **n1n2n3**.

7. core orthogonalization (default=off)

**CoreOrth** 1 logical — recently, this option is not maintained — Better to use local orbital instead, so that core charge do not spill out.

If this is on, we enforce cores orthogonalized to valence  $\phi$  and  $\dot{\phi}$  (these appear in II-C in Ref.I). This procedure enforce the correct orthogonal condition, thus we have correct behavior for the dielectric function at  $\mathbf{q} \rightarrow 0$ . However, it may deform core functions too much, especially in the case of shallow 3d (or maybe 4d) cores. So we don't recommend use this option, even though then the orthogonality condition is somehow broken. Anyway you can check weather it affects to results or not by this switch.

8. QP self-consistent GW.

**iSigMode** 1 integer (no default).

This is required for QSGW calculation by the script **gwsc**. We have some possible ways to make GW self-consistent (how we determine  $V_{xc}$  from calculated  $\Sigma(\omega)$ ). We now mostly use **iSigMode=3**.

3: Use  $\text{Re} \frac{\Sigma_{nn'}(\epsilon_n) + \Sigma_{nn'}(\epsilon_{n'})}{2}$  (mode-A in [?]).

1: Use  $\Sigma_{nn'}(E_F) + \delta_{nn'}(\Sigma_{nn'}(\epsilon_n) - \Sigma_{nn'}(E_F))$  (mode-B in [?]).

5: Use  $\delta_{nn'}\Sigma_{nn}(\epsilon_n)$  (Eigenvalue-only self-consistency, keeping the eigenfuncions as given)).

See **/gwsrsc/sxsf\_fa12.sc.F**, which is called from the main routine **hsfp0\_sc** (this is the routine to calculate self-energy)).

9. Others

**KeepEigen** 1 logical (default=on)

These are for memory usage. When KeepEigen is on, eigenfunctions (Eigen) are kept in memory during calculation. If you have not enough memory in your machine, use them off. Then you can save memory usage. However, then we may have too frequent access to files. So %CPU might get lower. Be careful to use these options.

**Verbose** 1 integer (default=0) If 0, it gives minimum standard output. If 40 or higher, it shows too much output. (these verbosity control is not well-organized yet).

10. **LFC@Gamma**, **EIBZmode**, **multitet** are for test purpose.xxx

## 10.4 <QPNT> section

(only for one-shot GW. Not suitable to make band plot in BZ.) This section is to specify the q points and bands index for which you calculate the QP energies (QPE). An example is

```
<QPNT>
--- Specify the q and band indeces, for which we evaluate the self-energy ---
*** all q -->1, otherwise 0; up only -->1, otherwise 0
          0          0
*** no. states and band index for calculation.
          3
15 16 17
*** q-points, which should be in qbz. See KPNTin1BZ.
          2
1      0.000000000000000000      0.000000000000000000      0.000000000000000000
```

```

2      0.2886751358562925    -0.5000000000000000    0.0000000000000000
3      0.0000000000000000    0.0000000000000000    0.3073140749846343
</QPNT>

```

Numbers are read by free format read(5,\*), thus the numbers should be separated by space. At the next line to the first **\*\*\***, you have to give two numbers used as flags. Both of them takes 0 or 1. 1st one is whether you calculate QPE for all q points (in IBZ) or not. If it is 1, you calculate QPE for all q. If it is 0, you calculate them only for q points specified within this file. In the case of metal where you want to calculate the Fermi energy for QPE, you need to calculate all the eigenvalues somehow above the Fermi energy (If you put 1, it is safer but too time-consuming). The second number is whether you calculate QPE for both spins or not. It is usually 0. In the case of antiferro material, it should be 1.

From the next line to the second **\*\*\***, you have to specify the states for which you calculate the QPE. In this example, you calculate the 3 bands of QPE for 15th, 16th, and 17th eigenfunctions (they are ordered from the bottom).

From the next line to the third **\*\*\***, you have to specify the q points. The first numbers of each line are dummy. In this case, you calculate QPE for two q points. The third q point is neglected because 2 is given at first.

When you generate GWinput.tmp, you see all the possible q points are listed (these q points should be a part of the regular mesh points).

In the QSGWmode (gwsc), this section is neglected (then we calculate all QPE on regular mesh points); so its hsfp0\_sc part is quite expensive (usually it takes time more than hx0fp0).

Additional Note —————

`QPNT_nbandrange` num1 num2 (two integers).

This override setting in <QPNT>. (I think this switch may still work, but not checked recently).

`AnyQ` on (default is off)

If this is on, you can specify any Q point which is not on the mesh point. For the purpose, we need to prepare eigenfunctions at extra **k** points. But it is automatic. In order to make the computation efficient. Even in this case, from the computational view, it is better to choose **q** on the two times finer divided mesh (or three times finer divided **k** mesh). This is used for Fig.6 in Phys. Rev. B 74, 245125 (2006).

## 10.5 set QPNT for eps mode (QforEPS section)

For eps modes (scripts `eps_*`, which are for linear responses. See Sec.15), you have to specify q point in the following ways.

1. `QforEPSIBZ` on

Then all Q point in IBZ are used.

2. Use section as

```
<QforEPS>
0d0 0d0 0.01d0
0d0 0d0 0.02d0
0d0 0d0 0.04d0
0d0 0d0 0.08d0
</QforEPS>
```

In addition, you can specify Q points as

```
<QforEPSL>
0d0 0d0 0d0 1d0 0d0 0d0 8
0d0 0d0 0d0 .5d0 .5d0 0d0 8
</QforEPSL>
```

This is along the line— 8 point along the line (not left-end q; so omitting 0 0 0). The first line means line (0d0 0d0 0d0)—(1d0 0d0 0d0) is divided to 8. So we have 7 points, (0.125 0 0), (0.25 0 0),... (1 0 0).

## 10.6 <PRODUCT\_BASIS> section

This section is to define product basis to expand  $W$  and so. Numbers are read by free format read(5,\*), thus the numbers should be separated by space. The line number in this section is meaningful (you can not add comment lines).

---

```

<PRODUCT_BASIS>

```

---

This section is read in the free format in fortran. So, e.g., 0.01 works as same as 0.10000D-01. The line order is important (you have to keep the order given by `GWinput.tmp`). Be careful atom atom id—lmf may re-order it and pass it to gw code. Look into LMTO file (generated by `mkGWIN_lmf2`); which contains crystal structure information after such re-ordering by lmf. I used ! to make clear that things after ! are comments. But ! is not meaningful – just the expected numbers of data separated by blank(s) are read for each line from the beginning of lines.

- 0.100000D-02 ! =tolopt controls a number of Product basis to expand the Coulomb interaction within MTs. tolopt is a criterion to remove the poorly linear-independent product basis. Note that the product basis, which is to expand the Coulomb interaction, is different from the basis to expand eigenfunctions. In our experience, 0.100000D-02 (=0.001) is not so bad. If you like to reduce computational time use 0.01 or so, but a little dangerous in cases. With 0.0001, we can check stability on it.  
(note: By supplying multiple numbers, we can specify tolopt atom by atom. Remember lmchk gives atom ID.)

- `lcutmx(atom)` is the  $l$  cutoff of product basis for atoms in the primitive cell (do `lmchk` for atom id). In the case of Oxygen, we can usually use `lcutmx=2` (need check by the difference when you use `lcutmx=2` or `lcutmx=4`). Then the computational time is reduced well.
- (dec2014:<PBASMAX> is not checked recently; see `fpgw/main/hbasfp0.m.F` and `fpgw/gwsr/basfnf.F`.) You can use <PBASMAX> section to override this setting. It is given as

```
<PBASMAX>
1  5 5 5 3 3
2  5 5 3 2 3
3  3 3 2 2 2
</PBASMAX>
```

The first number is for atom index (fixed), and other are product basis for each  $l$  channel.

- The integer numbers in 4th line `lcutmx` gives the maximum angular momentum  $l$  for the product basis for each atomic site. In our experience, `lcutmx=4` is required when the semi-core (or valence)  $3d$  electrons exist and we want to calculate the QP energies of them.
- Keep a block starting from "atom  $l$  nnvv nnc ..." as it originally generated in `GWinput.tmp`. It just shows that how many kinds of radial functions for cores and valence electrons for each atom and  $l$ . `nnvv=2` in the case of  $\phi$  and  $\dot{\phi}$ ; `nnvv=3` in the case to add the local orbital in addition.
- There are two blocks after the line "atom  $l$  n occ unocc :Valence(1=yes, 0=no)" and after "atom  $l$  n occ unocc ForX0 ForSxc ! Core (1=yes, 0=no)". These are used to choose atomic basis to construct the product basis. The product basis are generated from the products of two atomic basis.

`GWinput.tmp` generated by `mkGWIN_lmf2` contains labels on each orbitals as `4S_p`, `4S_d`, `4P_p`... Here `4S_p` is for  $\phi_{4s}$ ; `4S_d` for  $\dot{\phi}_{4s}$ ; `3D_l` for  $\phi_{3d}^{\text{local}}$ . Capital letter just after the principle-quantum number means the orbital is used as 'Head of MTO'; lowercase means just used only as the 'tail of MTO'.

The switches for columns labeled as `occ` and `unocc`. take 0 (not included) or 1 (included). With the switch, we can construct two groups of orbitals, `occ` and `unocc`. In this sample `GWIN_V2` as for atom 1,  $\{\phi_{4s}, \dot{\phi}_{4s}, \phi_{4p}, \phi_{4d}, \phi_{3d}^{\text{local}}, \phi_{3s}^{\text{core}}, \phi_{3p}^{\text{core}}\}$  consist the group `occ`, and  $\{\phi_{4s}, \phi_{4p}, \phi_{4d}, \phi_{3d}^{\text{local}}, \phi_{4f}\}$  consists the group `unocc`. So the any product of combinations  $\{\phi_{4s}, \dot{\phi}_{4s}, \phi_{4p}, \phi_{4d}, \phi_{3d}^{\text{local}}, \phi_{3s}^{\text{core}}, \phi_{3p}^{\text{core}}\} \times \{\phi_{4s}, \phi_{4p}, \phi_{4d}, \phi_{3d}^{\text{local}}, \phi_{4f}\}$  are included as for the basis of the product basis. As for atom 2,  $\{\phi_{2s}, \phi_{2p}, \phi_{3d}\} \times \{\phi_{2s}, \phi_{2p}, \phi_{3d}, \phi_{4f}\}$  are included.

- Core section: (not worth to read, since we currently use no `CORE2`, `A=B=C=0`.)

Each line of the last section of **Product BASIS** forms

```
atom  1      n  occ unocc  ForX0 ForSxc :CoreState(1=yes, 0=no)
   1    2    1    A     x      B     C
```

At first you have to understand the concept of `CORE1` and `CORE2` in EQ.35 Ref.I. However, in our recent calculations, we do not use "CORE2" generally. So, in such a case, set `A=B=C=0`. And treat shallow cores (above Efermi-2Ry or so) as valence electron by "local orbital method" in `lmf`.

- Be careful. Current version is inconvenient... Need to repeat `mkGWIN_lmf2` to generate `GWinput` template when you add PZ (local orbital).

[( Note: you can skip here if you don't use CORE2.)

Each of **A**,**x**,**B**,**C** takes 0 or 1. There are some possible combination of these switches;

1. If you take ( **A x B C** )= (1 0 1 1), then the core is included in core2. In other words, this core is treated in the same manner of the valence electron.
2. If you take ( **A x B C** )= (0 0 0 0), then the core is included in core1. The (exchange only) self-energy related to this core is included in **SEXcore**. **C** is the key switch which determine whether it is included in core1 or core2. There could be another option.
3. If you take ( **A x B C** )= (1 0 0 1). This core is in core2. But it is not included in the calculation of *D* and *W*. This core is only included for SEX and SEC calculations.

These three kinds of choices are reasonable ones but we can consider some another choice. In the following, we show how these switches (**A**,**B**,**C**) affect executions called from **gw\_lmfh** (essentially as same as **gw\_lmf**).

- **hbasfp0**(mode 3) :Product basis for exchange due to core.  
We include the **C**=0 cores as a part of the product basis as if **A**=1 **x**=0.
  - **hsfp0**(mode 3): exchange mode for core.  
 $\Sigma_x$  only due to the **C**=0 cores are calculated.
  - **hbasfp0** (mode1): Product basis.  
Only see the switch **A** and **x**. The product basis is generated from (occupied  $\times$  unoccupied), where **A**=1 core is included as one of the occupied basis.
  - **hsfp0** (mode 1): exchange mode.  
Only see the switch **C**.  $\Sigma_x$  due to valence and due to **C**=1 cores are calculated.
  - **hx0fp0** (mode 1): *W* – *v* calculation.  
Only see the switch **B**. *W* is calculates using all the valence and **B**=1 cores.
  - **hsfp0** (mode 2): correlation mode.  
Only see the switch **C**.  $\Sigma_c$  due to valence and due to **C**=1 are calculated.
- After you perform **gw\_lmfh** or anything, you find output files **lbas** by **hbasfp0** (mode1), and/or **lbasc** by **hbasfp0** (mode3) for core. These contains important information about how many and how product basis are chosen. E.g. '**grep nbloch lbas**' shows how many product basis are used in the calculations.

## 10.7 ANFcond (we can skip here since we do not check this option now. Need fix this if necessary.

This file is used in **hx0fp0** in the calculation of *W* – *v* (or rather  $\Pi$  in the program) to specify the antiferro condition.

**Note** : Now only for the case that (a translation vector + spin flip) is a symmetry operation.

This should be given by hand. For the cases of not antiferro, this file should not exist. Even if **ANFcond** does not exists for antiferro case, **hx0fp0** works but it requires about two time computational efforts.

The existence of this file means the Antiferro condition is used for x0k  
Product basis  $B(\{\mathbf{r}\}-\{\mathbf{a}\})$  is translated to  $B(\{\mathbf{r}\}-\{\mathbf{a}\}-\mathbf{Af})= B(\{\mathbf{r}\}-\{\mathbf{a}\}'-\mathbf{T}_0)$   
1d0 1d0 1d0 ! Af=Antiferro translation vector in Cartesian.  
1 2  
2 1  
3 4  
4 3

The first line specifies the Antiferro translation vector. From the second line, we specify that atom  $i$  in the primitive cell is mapped to what atom  $j(i)$  in the cell with the opposite spin by the translation. In this case,  $j(1) = 2, j(2) = 1, j(3) = 4, j(4) = 3$ . You have to be careful as for the true atomic position used in the GW calculations can be different from the given atomic positions in `ctrl.MnO`. The true atomic positions is written in `LMTO`.

In the case of one-shot GW (`gw_lmf` and `gw_lmfh`), it may be better to set "up only" QPE, so that you only calculate QPE of up spins at the same time.

In the case of `gwsc`, we just calculate QPE for up spins automatically (QPNT section is neglected).

## 11 Main Output Files of GW part

### 11.1 QPU

This is the main output<sup>13</sup> in human readable format.

An example of one-shot GW by **gw\_lmfn** is (In the case of QSGW,  $Z$  ( $Z = 1$ ) is not shown):

```
=====

...
```

From the 6h line, we have the eigenvalue data. All of the unit of energy is in eV. We should note that the zero-level of these values **eLDA eQP eQPnoZ** can be changed by **hqpe**. This **eLDA - E\_shift** are the eigenvalues relative to a Fermi energy determined by the smearing method. Detailed value of **eLDA** is in **TOTE2.UP**. Detailed value of **eLDA- E\_shift** is in **TOTE.UP**.

**q** : **k** vector

**state**: Band index  $n$ , which is from the lowest eigenvalue (not include cores).

**SEx**:  $= \langle \Psi_{\mathbf{k}n} | \Sigma_{\mathbf{x}}^{\text{core2+valence}}(\mathbf{r}, \mathbf{r}') | \Psi_{\mathbf{k}n} \rangle$

**SExcore**:  $= \langle \Psi_{\mathbf{k}n} | \Sigma_{\mathbf{x}}^{\text{core1}}(\mathbf{r}, \mathbf{r}') | \Psi_{\mathbf{k}n} \rangle$

**SEc**:  $= \langle \Psi_{\mathbf{k}n} | \Sigma_{\mathbf{c}}^{\text{core2+valence}}(\mathbf{r}, \mathbf{r}', \epsilon_n(\mathbf{k})) | \Psi_{\mathbf{k}n} \rangle$

**vxc**: LDA exchange correlation energy.  $\langle \Psi_{\mathbf{k}n} | V_{\mathbf{x}c}^{\text{LDA}}([n_{\text{total}}], \mathbf{r}) | \Psi_{\mathbf{k}n} \rangle$

**dSE**:  $Z_{n\mathbf{k}} \times \text{dSEnoZ}$

**dSEnoZ**:  $\langle \Psi_{\mathbf{k}n} | \Sigma_{\mathbf{x}}^{\text{core1}}(\mathbf{r}, \mathbf{r}') + \Sigma_{\mathbf{x}c}^{\text{core2+valence}}(\mathbf{r}, \mathbf{r}', \epsilon_n(\mathbf{k})) | \Psi_{\mathbf{k}n} \rangle - \langle \Psi_{\mathbf{k}n} | V_{\mathbf{x}c}^{\text{LDA}}([n_{\text{total}}], \mathbf{r}) | \Psi_{\mathbf{k}n} \rangle$   
 $= \text{SEx} + \text{SExcore} + \text{SEc} - \text{vxc}$

**eLDA**: LDA eigenvalues.  $\epsilon_n(\mathbf{k})$

**eQP**: QP energy.  $\epsilon_n(\mathbf{k}) + \text{dSE}$

**eQPnoZ**: QP energy without  $Z$ .  $\epsilon_n(\mathbf{k}) + \text{dSEnoZ}$

**eHF**: HF energy of 1st iteration.  $\epsilon_n(\mathbf{k}) + \text{SEx} + \text{SExcore} - \text{vxc}$

**Z**:  $Z$  factor.  $Z_{n\mathbf{k}}$

**2Z\*Simg**: Quasi-particle life time.  $2Z_{n\mathbf{k}} \times \text{Im} \langle \Psi_{\mathbf{k}n} | \Sigma_{\mathbf{c}}^{\text{core2+valence}}(\mathbf{r}, \mathbf{r}', \epsilon_n(\mathbf{k})) | \Psi_{\mathbf{k}n} \rangle$

(Is this really the usual definition of the life time?—don't believe me)

**ReS(eLda)**:  $\text{Re} \langle \Psi_{\mathbf{k}n} | \Sigma_{\mathbf{x}}^{\text{core1}}(\mathbf{r}, \mathbf{r}') + \Sigma_{\mathbf{x}c}^{\text{core2+valence}}(\mathbf{r}, \mathbf{r}', \epsilon_n(\mathbf{k})) | \Psi_{\mathbf{k}n} \rangle$

### 11.2 XCU

LDA exchange-correlation. Detailed data of above **vxc**.

### 11.3 SEXU

Exchange part of the self-energy due to valence electrons. Detailed data of above **SEx**.

### 11.4 SEXcoreU

Exchange part of the self-energy due to core. Detailed data of above **SExcore**.

<sup>13</sup>Note that QPU also implies QPD and so on. U is for up D is for down spins.

## 11.5 SECU

Correlation part of the self-energy. Detailed data of above SEc.

## 11.6 TOTE.UP (TOTE.DN)

This is a central output. It contains LDA and QP energies. These values are relative to a Fermi energy determined by the smearing method. It contains two kind of QP energies QP QPnoZ. The first line contains the Fermi energy in Ry determined by the smearing method. It is also shown in the end of DOSACC.Ida.

## 11.7 TOTE2.UP (TOTE2.DN)

This is a central output. It contains zero-level shifts from TOTE.UP. The first line contains the Fermi energy in eV (= the Fermi energy in TOTE.UP but it is in Ry) and three energy shifts E\_shift, which are the same values in the 4th line of QPU.

Note that all \*.chk files are just to check calculations (not read in by successive executions).

## 11.8 DOSACC.Ida

This lists all the eigenvalues in ascendant order. States with almost the same eigenvalues are degenerated states. The 4th column contains number of electrons up to the eigenvalue.

## 11.9 DOSACC2.Ida

This is similar with DOSACC.Ida. But we remove the degeneracy.

## 11.10 Core\_ibas\*.\*.chk

Used core eigenfunctions.

## 11.11 VXCFP.chk

This contains eigenvalues and  $\langle \psi_{\mathbf{k}n} | V_{\text{xc}} | \psi_{\mathbf{k}n} \rangle$  in both units, Ry and eV. See below.

## 11.12 The Fermi energies in this GWcode.

We mainly have two kinds of Fermi energy  $E_{\text{FEERMI}}^{\text{smear}}$   $E_{\text{FEERMI}}^{\text{tetra}}$ .

1. At first eigenvalues given by **lmfgw** is in VXCFP.chk. You can see

```
%head VXCFP.chk
### LDA exchange correlation ###
#   qvec                ikp iband    eigen      VXC(ntotal)      VXC(nvalence)      eigen(eV)
  0.0000  0.0000  0.0000  1  1      -0.96932423      -1.00727912      0.00000000      -13.18843159
...
```

These are raw values. TOTE contains the eigenvalues but relative to a Fermi energy  $E_{\text{FEERMI}}^{\text{smear}}$  which is determined by the smearing method. It is also shown at the top part of output files lxx\_sf and lsc\_sf. And you also see the value at the end of DOSACC.Ida.

This is the head of TOTE.UP;

%head TOTE.UP

```

      43      8  8.520283353474250E-003
      0.0000000  0.0000000  0.0000000  1  1  -0.1330435686590073D+02 -0.1322984339282777D+02
      0.0000000  0.0000000  0.0000000  2  1  -0.7555264915356062D+00 -0.6267595395613325D+00
...

```

Here  $E_{\text{FEERMI}}^{\text{smear}}=8.520283353474250\text{E-}003$ . From the second lines, they are LDA eigenvalues and QP energies (Z included and Z=1); they are relative to the  $E_{\text{FEERMI}}^{\text{smear}}$ .

-13.18843159 eV -  $E_{\text{FEERMI}}^{\text{smear}}$  (which should be translated into in eV) = -0.1330435686590073D+02 eV. Here -13.18843159 is the value in VXCFF.chk shown above.

2. There is the another Fermi energy  $E_{\text{FEERMI}}^{\text{tetra}}$ , which is used by mode 11 (or mode 1) of `hx0fp0` in `gw_lmfh`. It is determined by `heftet` and stored in `EFERMI`.
3. `hqpe` gives `TOTE2.UP` and `QPU`. They contains the same values. You can see `eLDA eQP eQPnoZ Z` not only in `QPU` but also in `TOTE2.UP`. At top lines of `TOTE2.UP`, you see

%head TOTE2.UP

```

      43      8  0.1159252712507000D+00  0.7555207081466229D+00  0.6267572296579150D+00  0.6
      0.0000000  0.0000000  0.0000000  1  1  -0.1254883615775411D+02 -0.1260308616316985D+02
      0.0000000  0.0000000  0.0000000  2  1  -0.5783388983382487D-05 -0.2309903417430093D-05
      0.0000000  0.0000000  0.0000000  3  1  -0.1369098933889923D-05 -0.6195200397129952D-07
      0.0000000  0.0000000  0.0000000  4  1  0.0000000000000000D+00  0.0000000000000000D+00
..

```

, where a number in first line  $E_{\text{FEERMI}}^{\text{smear}}=0.1159252712507000\text{D}+00$  eV = 8.520283353474250E-003 Ry, the same as the previous one. This is a case when you did `hqpe` with augment 4 (it means we set the 4th-band eigenvalue zero). Another 3 values in the first line are shifts from `TOTE`. Shown `eshift(eLDA) = 0.7555207081466229D+00` eV. E.g., the second line shows -0.1254883615775411D+02 eV = -0.1330435686590073D+02 (in `TOTE`) + `eshift(eLDA)` eV.

When you do `hqpe metal`, three shifts at the first line in `TOTE2.UP` is determined so as to give the eigenvalues relative to the Fermi energies shown in `EFERMI`, `EFERMI.QP1`, and `EFERMI.QPz=1`. These are Fermi energies by tetrahedron method.

As for `gwband_lmf`, it recalculates eigenvalues for all **q** along SYML. Then the default "zerolevel" =  $E_{\text{FEERMI}}^{\text{smear}} - \text{eshift(lda)}$ . Because the eigenvalues given by this band-mode are presumably the same, we have

Shown LDA eigenvalue

```

= -13.18843159 (raw data by band mode—same as that in VXCFF.chk) - zerolevel
= (-13.18843159 - EFERMIsmear) + eshift(lda).
= -0.1330435686590073D+02 ( this is in TOTE.UP) + eshift(lda)
= -0.1254883615775411D+02 ( this is in TOTE2.UP).

```

It means that values in `TOTE2.UP` recovers. But if raw data by band mode is different from it, these is a trouble. It does not recover the values in `TOTE2.UP(=QPU)`.

As for the QPE, we calculate the difference from LDA values in `TOTE2.UP` at first, and add the difference to the Shown LDA eigenvalue.

## 12 mkGWIN\_lmf2 and its I/O Files

(QPNT.chk contains irreducible k point for given n1 n2 n3; KPTin1BZ.gwinit.chk contain all k points in Brillouin Zone).

The purpose of the script **mkGWIN\_lmf2** is to give a template **GWinput.tmp**. The script is complicated because of historical reasons. However, its essential is simple; we calls three executions in this script as

**echo 0 | lmf gw si**

**echo 1 | gwinit**

**echo -100 | qg4gw**

. We explain each by each.

### 12.1 echo 0|lmf gw

— makes SYMOPS LATTC CLASS NLAindx.

Input files

- **GWINO** : This is a file, which contains your supplied n1 n2 n3 when you invoke the script. This file is given within the script of mkGWIN\_lmf2 (as "here document").

```
cat <<EOF >GWINO
n1 n2 n3
  $n1 $n2 $n3
cut
  4.0 3.0
alpha
  1
Number of bands
  999 99999.0
  999 3.0
EOF
```

- **ctrl.si** : Master input file of lmf calculation.

Output files

- **LATTC** : contains the information of primitive translation vectors, lmxa and konf. See ??
- **SYMOPS** : The point group operations. See ??
- **CLASS** : Equivalent atomic positions are called as 'class'. This small file contains a map between atomic site and 'class'.
- **NLAindx** : This file contains indexes ( $p_{\text{valence}}, l, a$ ) for orbitals in the MT. ( $p_{\text{valence}}$  is radial function index,  $a$  is atomic site index). Eigenfunctions are expanded in this order.
- **ldima** : Number of MTOs for each atomic site. (this is used only from **hqpe.sc**—QSGW mode).
- **ves\*** : not meaningful at this stage
- **rhoMT\*** : not meaningful at this stage

### 12.2 gwinit

— Get GWIN\_V2.tmp and QPNT.tmp

Input files

- **GWINO** :
- **LATTC** :
- **SYMOPS** :
- **NLAindx** :

Output files

- **GWIN\_V2.tmp** : A part of GWinput.tmp
- **QPNT.tmp** : A part of GWinput.tmp
- (**KPNTin1BZ.gwinit.chk**) : check KPNT in the 1BZ.

If SYML exist, **gwinit** gives also a template **QPNTforSYML.tmp** suitable for such SYML. Here SYML specify how to plot the energy band. See explanation for **bandplot** script.

Note that LATTC SYMOPS CLASS NLAindx are overwritten when you execute **gw\_lmfh** because we repeat **echo 0|lmf** at the head of **gw\_lmfh**.

### 12.3 echo -100|qg4gw

— Generate GWinput.tmp

Input files

- GWIN0 : (copy of GWIN0.tmp by **gwinit**)
- GWIN\_V2 : (copy of GWIN\_V2.tmp by **gwinit**)
- QPNT : (copy of QPNT.tmp by **gwinit**)

Output files

- GWinput : (this is copied to GWinput.tmp)

This command "echo -100|qg4gw" is a file converter from these two files into GWinput. And it is copied to GWinput.tmp. (**mkGIN\_lmf** keeps GWinput if it exist before you invoke it.).

### 13 gwsc script and its I/O Files

In **gwsc**, we have a loop of QSGW self-consistency. Look into the **gwsc** script. In each iteration, we perform these fortran programs;

```
NO_MPI=0 #this is used for non-mpi versions of fortran program.

### self-consistent calculation for given Sigma(self-energy) ###

    run_arg '---' $MPI_SIZE $nfpwgw /lmf-MPIK    llmf $TARGET

### Preparation stage #####

argin=0; run_arg $argin $NO_MPI $nfpwgw /lmfgw      llmf gw00 $TARGET
argin=1; run_arg $argin $NO_MPI $nfpwgw /qg4gw      lqg4gw #Generate required q+G v
argin=1; run_arg $argin $MPI_SIZE $nfpwgw /lmfgw-MPIK llmf gw01 $TARGET
        run_arg '---' $NO_MPI $nfpwgw /lmf2gw      llmf2gw #reform data for gw

### Main stage of gw #####

argin=0; run_arg $argin $NO_MPI $nfpwgw /rdata4gw_v2 lrd4gw_v2 #prepare files
argin=1; run_arg $argin $NO_MPI $nfpwgw /hefttet     leftet # A file EFERMI for hx0fp0
argin=1; run_arg $argin $NO_MPI $nfpwgw /hchknw      lchknw # A file NW, containing nw

## Core part of the self-energy (exchange only) ##

argin=3; run_arg $argin $NO_MPI $nfpwgw /hbasfp0      lbasC # Product basis generation
argin=3; run_arg $argin $MPI_SIZE $nfpwgw /hvccfp0    lvccC # Coulomb matrix for lbasC
argin=3; run_arg $argin $MPI_SIZE $nfpwgw /hsfp0_sc    lsxC # Sigma from core1

## Valence part of the self-energy Sigma ##

argin=0; run_arg $argin $NO_MPI $nfpwgw /hbasfp0      lbas # Product basis generation
argin=0; run_arg $argin $MPI_SIZE $nfpwgw /hvccfp0    lvcc # Coulomb matrix for lbas
argin=1; run_arg $argin $MPI_SIZE $nfpwgw /hsfp0_sc    lsx # Exchange Sigma
argin=11; run_arg $argin $MPI_SIZE $nfpwgw /hx0fp0_sc  lx0 $lx0_para_option #x0 part
argin=2; run_arg $argin $MPI_SIZE $nfpwgw /hsfp0_sc    lsc #correlation Sigma
argin=0; run_arg $argin $NO_MPI $nfpwgw /hqpe_sc      lqpe #all Sigma are combined.

run_arg:
```

Here a subroutine of bash **run\_arg** was used, which is given in `ecalj/lm7K`; it just invoke a command with the argument **\$argin** (this is read by `read(*,*)` in fortran). In cases with `MPI_SIZE/=0`, `mpirun` is invoked. Console out put go to `l*` files. For example,

```
    argin=2; run_arg $argin $MPI_SIZE $nfpwgw /hsfp0_sc lsc #correlation Sigma
```

invokes **hsfp0\_sc** with argument '2' by `mpirun` with the `-np $MPI_SIZE`. Console outputs are written into logfiles such as `lqpe`. **\$nfpwgw** contains path to the execution binaries.

In the following, We explain input/output files for each fortran program. Note that “**echo 0|lmfgw**” means invoking **lmfgw** with **argin=0**.

### 13.1 echo 0| lmfgw si

See Sec.12.1.

### 13.2 echo 1| qg4gw

This makes **q** points, and **G** vectors for these **q**. (**q** was **k** in previous sections.) Main routine of qg4gw is fpgw/main/qg4gw.m.F and calls fpgw/gwsrsc/mkqg.F

Input files

- GWinput :
- LATTC :
- SYMOPS :

Output files

- QGpsi : (bin) q and G vector for the eigenfunctions.
- QGcou : (bin) q and G vector for the Coulomb matrix
- Q0P : offset- $\Gamma$  points which are the replacement of the  $q=0$  points. See section??.
- QIBZ : q points in the Irreducible BZ.
- BZDATA : (bin) BZ data for integration (include tetrahedrons if necessary). See e.g. main/hxOfp0.sc.F and search "call read\_BZDATA", which is a readin routine of this file defined in rwbzdata.F.
- KPTin1BZ.mkqg.chk : list of q in the 1st BZ for check.
- QBZ : q point in the 1st BZ.
- EPSwklm : Required information for the BZ integration (mainly in order to evaluate the weight in the  $\Gamma$  cell). See Eq.xxx in [?].

### 13.3 echo 1|lmfgw si

Calculate eigenfunctions, eigenvalues and  $\langle\psi|H_{KS}|\psi\rangle$

Input files

- ctrl.si :
- rst.si : (bin) Restart file of the lmf calculation. It contains all information
- sigm.si : (bin) If this exist and
- QGpsi, QGcou, Q0P : :
- NLAindx : :

Output files

- gwa.si : (bin) atomic data
- gwb.si : (bin) band data
- gw1.si : (bin)  $\langle\psi|H_{KS}|\psi\rangle$
- gw2.si : (bin)  $\langle\psi|H_{KS} - V_{xc}(n_{total})|\psi\rangle$ .
- vxc.si, evec.si : (bin) used in hqpe.sc.m.f as "v\_xc" and "evec").

vxc.si contains  $\langle\psi|V_{xc}(n_{total})|\psi\rangle$  including off-diagonal part. evec.si contains eigenfunctions.

- normchk.si : norm check (only for check) This is like this

```
> head -20 normchk.si
#      IPW      IPW(diag)      Onsite(tot)      Onsite(phi)      Total
      0.436015      0.805123      0.563972      0.562573      0.999988
      0.339134      0.620353      0.660515      0.656881      0.999649
      0.339133      0.620353      0.660516      0.656882      0.999649
      0.339133      0.620353      0.660516      0.656882      0.999649
      0.507738      0.648515      0.492040      0.487673      0.999778
...
```

This check is sometimes important for debugging and to determine the cutoff parameter **QGcut\_psi**. The first line (corresponding to 1st band of 1st q point) means that total normalization almost unity = 0.999988 = 0.436015 + 0.563972. Because we expand the MTO by IPW, the normalization is a bit different from unity, especially for higher bands. You can see that it get closer to unity for larger QGcut\_psi, though it does not reach to unity because of some contribution of the higher angular momentum contribution within MT. [Values of Onsite(phi) are not correctly shown in the case when you use local orbital.]

Due to historical reason, data in vxc.si and exec.si and others contains duplicated data.

## 13.4 lmf2gw

All the required information are stored into DATA4GW\_V2 and CphiGeig.

### Input files

- gwa.si :
- gwb.si :
- gw1.si :
- gw2.si :
- Q0P :
- CLASS :
- NLAindx :

### Output files

- DATA4GW\_V2 : (bin) Main data for GW calculations.  
I/O of DATA4GW\_V2 is controlled by `gwinput.f`, which contains detailed information.
- CphiGeig : (bin) Eigenfunctions for GW calculations.
- VXCFP.chk : Eigenvalue and Vxc check (only used for check)  
It is like this;

```
### LDA exchange correlation ###
#   qvec      ikp iband   eigen   VXC(ntotal)   VXC(nvalence)   eigen(eV)   VXC(ntotal)(eV)   VXC(nvalence)
0.0000 0.0000 0.0000 1 1   -0.68505346   -0.91850436   0.00000000   -9.32070032   -12.49698668   0.00000000
0.0000 0.0000 0.0000 1 2    0.19292662   -0.99853478   0.00000000    2.62492096   -13.58586453   0.00000000
0.0000 0.0000 0.0000 1 3    0.19292763   -0.99853469   0.00000000    2.62493477   -13.58586334   0.00000000
0.0000 0.0000 0.0000 1 4    0.19292777   -0.99853461   0.00000000    2.62493664   -13.58586222   0.00000000
...
```

Here `VXC(nvalence)` is not used now. The eigenvalue in `eigen` is in Ry.

— This is the end of the preparation stage. —

From here, the main stage.

## 13.5 rdata4gw\_v2

— Read DATA4GW\_V2 and some files, and decompose it into files required in the following GWsteps. (checked! dec2014)

### Input files

- GWinput :
- DATA4GW\_V2 :
- CphiGeig :
- QGpsi :
- QGcou :
- Q0P :
- QIBZ :
- SYMOPS : points group operations.

### Output files

- hbe.d : data size
- Coreibas\*.\*.chk : core eigenfunctions just for check.
- LMTO : basic data for the crystal.
- EValue : (bin) valence eigen value
- ECORE : core data and core eigenvalues
- CPHI : (bin) Coefficients of eigenfunctions as for the atomic-like argumentation waves in MTs'.
- GEIG : (bin) Coefficients of eigenfunctions as for IPW.
- PHIVC : (bin) All the radial functions.
- @MNLA.CPHI : index set for CPHI. This is not refereed just a check write.
- @MNLA.core : index set for core. This is not refereed just a check write.
- VXCFP : (bin) this is for diagonal elements of  $V_{xc}^{LDA}(n_{total})$ .
- PPOVLI.\* : (bin) Overlap matrix of IPW. xxxxxxxxxxxx

- PPOVLG.\* : (bin) PPOVLG Overlap matrix xxxxxxxxxxxxf IPW. not exactly the the overlap matrix. see around line 500 in rdata4gw.m.f
- PPOVL0 : (bin) xxxxxxxxxxxxxx
- HVCCIN : (bin) Required inputs for hvccfp0. Information in this files.
- NQIBZ : q point info. Only used for parallel test mode.
- normchk.dia : Norm check. These numbers should be almost the same as those in normchk.si

These files are input for the following steps. The name of file *fooU* means that it relates to up-spin. We have *fooD* files in the case of spin-polarized calculation with **nspin=2**.

### 13.6 echo 1|heftet

— Get the Fermi energy EFERMI by tetrahedron method. It is used in **hx0fp0**.

Input files

- EVU :
- BZDATA :
- GWinput :
- ECORE : (dummy)
- SYMOPS : (dummy)
- LMTO :
- hbe.d :

Output files

- EFERMI : contains Fermi energy given by the tetrahedron method. It is used in **hx0fp0** but not in **hsfp0**.
- DOSACC.la,DOSACC2.la : They are lists of the all the eigenvalues from the bottom. DOSACC2.la is a list to show only the un-degenerated eigenvalues. They are just check write. But it is an indicator for you to determine **esmr** in GWinput.

### 13.7 hchknw

— Calculate the required number of  $\omega$  points along real axis.

This NW is not essentially used in **gw\_lmfh** (but required as a dummy file). Only used in **gw\_lmf**.

Input files

- BZDATA :
- GWinput :
- ECORE : (dummy)
- SYMOPS : (dummy)

Output files

- NW : contains number of  $\omega$  points.

### 13.8 echo 3|hbasfp0

— Make product basis.

Mode 3 is for the core states. It generate a product basis on each MT suitable to expand to calculate the exchange part due to core. See explanations for the input file of GWinput.

Input files

- LMTO :
- PHIVC :
- GWinput :

Output files

- BASFP\* : (bin) Product basis functions
- PPBRD\_V2.\* : (bin) Radial integrals on each MT, symbolically written as  $\int \phi(r)\phi(r)B(r)dr$
- PHIV.chk : Valence radial functions (for check).

### 13.9 echo 0|hvccfp0

— Calculate the Coulomb matrix in the Mixed basis

Input files

- HVCCIN :
- Q0P :
- BASFP\* :

Output files

- VCCFP : The Coulomb matrix expanded in the mixed basis
- Mix0vec : This is used only for dielectric-constant calculation (mode 2 or 3 of **hx0fp0**). This contains the expansion of the plane wave  $\exp(i\mathbf{q}\mathbf{r})$  in the mixed basis. See Usuda's note.

### 13.10 echo 3|hsfp0

— Exchange part of the self-energy for the core

Input files

- GWIN\_V2,LMTO,ECORE :
- CLASS :
- hbe.d :
- Q0P :
- PPBRD\_V2\_\* :
- CPHI :
- GEIG :
- VCCFP :
- PPOVL :

Output files

- SEXcoreU : The core part of the exchange self-energy for  $\mathbf{q}$  and band index specified in  $\langle\text{QPNT}\rangle$ . See ??.

### 13.11 echo 0|hsfp0

— Make product basis for the valence part.

### 13.12 echo 1|hsfp0

— Exchange part of the self-energy for the valence part.

Output files

- XCU : The LDA exchange self-energy for  $\mathbf{q}$  and band index specified in  $\langle\text{QPNT}\rangle$ . See ??.
- SEXU : The valence part of the exchange self-energy for  $\mathbf{q}$  and band index specified in  $\langle\text{QPNT}\rangle$ . See ??.

### 13.13 echo 11|hx0fp0

— Screened Coulomb interaction  $W$  (Sergey mode)

Input files

- GWinput, LMTO, Ecore, EVU :
- NW : dummy
- hbe.d :
- Q0P :
- PPBRD\_V2\_\* :
- CPHI,GEIG :
- PPOVL :
- VCCFP :
- ANFcond : (optional) This file is to specify antiferro condition. This should not exist for other cases. This file should be given by hand.

Output files

- WV.d : size of the dielectric function
- WVR : (bin)  $W - v$  in the expansion of mixed basis along the real axis

- WVI : (bin)  $W - v$  in the expansion of mixed basis along the imaginary axis

### 13.14 echo 12|hsfp0

— Correlation part of the self-energy(Sergey mode)

Input files

- GWinput, LMTO, Ecore, SYMOPS : These are readin by **genallcf\_v3**.
- CLASS, hbe.d, EVU, Q0P :
- PPBRD\_V2.\* :

Radial integrals on each MT, symbolically written as  $\int \phi(r)\phi(r)B(r)dr$ . These are generated by **hbasfp0**.

- CPHI,GEIG :
- PPOVL :
- WV.d, WVR, WVI :

Output files

- SECU : The correlation part of the self-energy for **q** and band index specified in **<QPNT>**. See ??.

### 13.15 echo 0|hqpe

— Summarize the output

Input files

- SEXcoreU,XCU,SEXU,SECU : See ??.

Output files

- QPU : The QP energies and related value summary in human interface. See ??.
- TOTE : The detailed values of the QP energies. See ??.
- TOTE2 : The detailed values of the QP energy. See ??.

NOTE: For example, if you do **{echo 4|\$hqpe}{hqpe}**, it just shift zero level of QPE, so that 4th line (counted from top) eigenvalue (in QPU) is to be zero.

## 14 Check list for convergence on GW calculations

Results could be dependent on cutoff parameters in **GWinput**. In my opinion, generally speaking, it is so easy to have convergence more than  $\sim 0.1\text{eV}$  for band gap...

- Number of k points `n1n2n3`.

Probably  $4 \times 4 \times 4$  (or  $6 \times 6 \times 6$ ) are reasonable choice for insulator in the case of two atoms such as GaAs. In other words, “used periodic cell volume” =  $4 \times 4 \times 4 \times (\# \text{ of atoms}) \times (\text{Volume per atom})$ . For example, for  $2 \times 2^3 = 16$  atoms per cell, we can use  $2 \times 2 \times 2$  instead of  $4 \times 4 \times 4$  (this is the same as in the case of LDA).

For metals,  $12 \times 12 \times 12$  or more per atom may be required. But it depends on case by case.

- MTO’s and APWs. Basis for eigenfunctions.

If we like to get “best converged results, we may need to use large enough MTO’s. (I think the default setting is reasonable; but there is a room to change MTO settings in `ctrl.*`). But, in cases, we can not use large APW cutoff (`pwemax`) more than  $3.0 \sim 4.0$  Ry because of poor linear dependency of basis set (calculation in LDA level fails). In such a case, we need to use “smaller MT radius `R=`”. Then we may need semi-core as local orbital when “its spillout in the outside of MTs is too large”.

In **GWinput**, we can set the number of unoccupied states which you take into account by `emax_chi0`, `emax_sign`, `nband_chi0`, and `nband_sign`. But we usually unset them except `emax_sign` for **gws**.

(We may need a kind of completeness of the basis set; the completeness could be important from the view of ‘Coulomb hole’ picture.)

NOTE: Current PMT-QSGW method [?] expand the static version of self-energy of QSGW just in the basis of MTO’s (no APWs). Thus the expansion can be unsatisfactory (it depends on case by case, and required convergence). In such a case, we inevitably have to use empty spheres (MTO’s) which is for empty region.

- Cores.

We usually use all cores as **core1** (exchange only core). If necessary, it is better to treat shallow cores by the local orbitals (such cores are treated as valence).

If we treat cores by **core2** (not only for exchange, but also in dielectric functions), we have to be careful about the core wave orthogonalization with respect to valence eigenfunctions; this is a little complicated; probably it is better not to use **core2**.

(This is related to `CoreOrth` (only for core2). If it affects so much, *D* function might be too poor due to the poor orthogonality condition between core and valence.) (NOTE: `CoreOrth` is not maintained recently)

- `QpGcut_psi` IPW cutoff to expand eigenfunctions in the interstitial region. We usually use `QpGcut_psi 4.0`. Usually not so bad. Larger is better but expensive. You may test calculations with `QpGcut_psi 3.0`, and how much difference of results.
- `QpGcut_cou` IPW cutoff to expand the Coulomb interaction in the interstitial region (Mixed product basis(MPB) consist of this IPW and PB). interstitial region. We usually use `QpGcut_cou 3.0`. Usually not so bad. Larger is better but expensive. You may test calculations with `QpGcut_cou 2.5`, and how much difference of results.
- Product basis section.  
At least, `1cutmx=4` will be necessary for atoms with d electrons. (but `1cutmx=2` look reasonable for oxygen, for example).
- `esmr`.  
In our experience, `esmr=0.003000` (default) is reasonable. But there is a room to check stability on it for metals. In principle, for larger `n1n2n3`, we can use smaller `esmr`.
- `dw, omg_c niw`

It will be worth to try to check how much the results changed due to them. But usually `dw=0.005`, `omg_c=0.04` is not so bad a choice. As for `niw=10` seems to be not so bad usually, but it is safer to check the convergence on it (test cases with `niw=6,10,12,16`).

- `deltaw`.  $\sim 0.01$  a.u. will be not so bad. See two Z values shown in SXCU. It is better to try to check how about the dependence on this.
- `chi_regqbz off`. (on is default). If off, we use off-Gamma mesh (Gamma point is between mesh points) for dielectric functions when we perform GW or QSGW. “chi\_regqbz off” may accelerate convergence on number of k points.

## 15 Linear response calculations

With these scripts for linear response calculations, **eps\***, we can calculate **q**-dependent dielectric function  $\epsilon(\omega, \mathbf{q})$  (and  $v$ ,  $W$ ) (and  $\chi$  for spin fluctuation). But (because of numerical reason), we can not use  $\mathbf{q} = 0$  limit. (if  $|\mathbf{q}|$  is too small, we have numerical problem, zero divided by zero, because we have not implemented the version to use  $\mathbf{q} = 0$ .)

- **eps\_lmfh**  
Dielectric function epsilon with local field correction. Expensive calculation (we may need to reduce number of wing parts in future...).
- **epsPP\_lmfh**  
epsilon without local field correction.  $1 - \langle e^{i\mathbf{q}\mathbf{r}} | v | e^{i\mathbf{q}\mathbf{r}} \rangle \langle e^{i\mathbf{q}\mathbf{r}} | (\chi^0) | e^{i\mathbf{q}\mathbf{r}} \rangle$
- **epsPP\_lmfh\_chipm**  
For spin susceptibility. This essentially calculate non-interacting spin susceptibility. Then it is used for the calculation of full spin susceptibility with **util/calj\_\*.F** programs (small quick programs). See spin wave paper. See spin susceptibility section Sec.??.
- (not maintained now; we will recover this) **eps\_lmfh\_chipm**  
This gives full non-interacting spin susceptibility. Testing. We have to determine  $U$  (Stoner  $I$ ) for the determination of full spin susceptibility. TDLDA? or so?
- (This is old mode --- not maintained) **epsPP\_lmfh\_chipm\_q**  
For spin susceptibility, spin susceptibility  $\langle e^{i\mathbf{q}\mathbf{r}} | \chi(q, \omega) | e^{i\mathbf{q}\mathbf{r}} \rangle$  In this script, You have to assign that isp=1 is majority, isp=2 is minority. This is with long wave approximation.

- 
- We use the histogram method (the Hilbert transformation method); we first calculate its imaginary parts with the tetrahedron technique for dielectric functions. Then we get its real part by the Hilbert transformation.

You need to choose `[dw, omg_c]`. The width of histogram bins are getting larger when omega gets larger. dw is the size of histogram-bin width at omega=0. At omega=omg\_c, its width gets twiced.

To plot dielectric function with reasonable resolution, it might be better to set **dw** 0.001 and **omg\_c** 0.1 for example. You may have to choose small enough omega for spin wave mode as 0.001 Ry (Or smaller). omg\_c is given like 0.05 Ry or so. But sometimes it can be like 1Ry.

- **epsPP\_lmfh** only calculation an matrix element of dielectric function for  $\exp(i\mathbf{q}\mathbf{r})$ . Thus very faster than **eps\_lmfh** mode. It uses a a special product basis set for cases without inversion (problem is in how to expand  $\exp(i\mathbf{q}\mathbf{r})$  in the MPB; the product basis is not from phi and phidot, but from spherical Bessel functions).

In **\*\_lmfh\_\*** modes( I now use little for **\*\_lmf\_\*** modes), you can use small enough delta. Use small enough delta ( $\approx 10^{-8}$  a.u.) for spin wave modes (also you can use it for dielectric function and GW). This is necessary because pole is too smeared if you use larger delta.

### 15.1 eps\_lmfh, epsPP\_lmfh: the dielectric functions

You can invoke the script, e.g. as **"eps\_lmfh si"**.

---

Specify **q** point in **<QforEPS>** or so. Mesh for  $\omega$  is specified by `[dw, omg_c]`.

The obtained data are in **EPS\*.dat** and **EPS\*.nlfc.dat**. **EPS\*.nlfc.dat** contains the result without local-field correction **EPS\*.dat** contains the result with local-field correction (this is generated only for **eps\_lmfh**. Both of them contains

**q(1:3)**,  $\omega$ ,  $\text{Re}(\epsilon)$   $\text{Im}(\epsilon)$ ,  $\text{Re}(1/\epsilon)$ ,  $\text{Im}(1/\epsilon)$

in each line.

- This code works OK only for **q** is near 0. Be careful for  $\mathbf{q} \rightarrow 0$  limit. Too small **q** can give strange spectrum at high energy (real part is affected by it)

Because  $\mathbf{q} \rightarrow 0$  gives too large cancellation effects (the denominator and numerator go to zero—it means we need very accurate orthogonalization between occupied and unoccupied states). This is a kind of disadvantage of our method (though there is an advantage— our code can calculate dielectric function even for metal as far as you use large enough number of  $\mathbf{k}$  point.)

- The calculate of dielectric functions usually requires so many  $k$  point. For example, for Si,  $n_1\ n_2\ n_3 = 4\ 4\ 4$  is too small. It gives too large dielectric constants  $\sim 19.4$  though the converged value should be  $\sim 13$ . (we need  $10 \times 10 \times 10$  or more like  $20 \times 20 \times 20$  for some reasonable results). For GaAs, we observed that reasonable  $\epsilon(\omega)$  requires rather large number of  $\mathbf{q}$  points like  $15 \times 15 \times 15$  or  $20 \times 20 \times 20$  for `n1n2n3`. This is too time-consuming to get result (but you can use “very small product basis”(just sp polarization for this purpose; it makes speed up so much). Or, you can calculate “ $\epsilon(\omega)$  without LFC”. See section for `eps_PP_lmfh`.

- Core orthogonalization problem (only when `core2` is used)  
—`CoreOrth` is not maintained recently — `CoreOrth` gives so serious effect for  $\epsilon(\omega)$ , if you include some cores as “`core2`” in the product basis setting. (This means that you includes transitions from “`core2` to valence” in the calculation of  $\epsilon(\omega)$ ).

Then you have to use “`CoreOrth on`”. Without it, you will have rather large imaginary part at rather high energy. Such transitions from core to higher valence bands is artificial due to the incomplete orthogonality between core and the higher bands. However, shallow  $d$  semi-core might be deformed too much by this option. Try to plot `Core_*.chk` files, which contains core radial functions. Anyway, it is better to treat shallow core as valence by “local orbital”.

## 15.2 epsPP\_lmfh: the dielectric function(No LFC— faster)

You can calculate  $\epsilon$  without LFC by `epsPP_lmfh`. It is very faster than `eps_lmfh`.

To calculate  $\epsilon(\mathbf{q}, \omega)$  without LFC accurately, the best basis set for the expansion of the Coulomb matrix within MT is apparently not the product basis, but the Bessel functions corresponding to the plane waves  $\exp(i\mathbf{q}\mathbf{r})$ . We use such a basis in this mode. However, our experience shows that the changes are little even with the usual product basis (we don’t describe this here).

## 15.3 How to calculate correct dielectric function?

(this subsection is essentially OK... but need to clean it up. dec2014)

There are problems to calculate correct epsilon.

At first, we talk about `epsPP_lmfh`, which is No LFC. Main problem are

-----

1. Convergence for number of  $\mathbf{k}$  point(specified by `n1n2n3`).

Roughly speaking,  $20 \times 20 \times 20$  is required for not-so-bad results for Fe and Ni.

It is better to do  $30 \times 30 \times 30$  to see convergence check.

However, in the case of ZB-MnAs (maybe because of simple structure around Ef), it requires less  $\mathbf{q}$  points.

figs are for GaAs.

fig001: `n1n2n3` convergence for `Chi_RegQbz = on` case.

fig002: `n1n2n3` convergence for `Chi_RegQbz = off` case.

(`Chi_RegQbz` is explained in General section in this manual).

As you see,  $\mathbf{k}$  points convergence looks a little better in `Chi_RegQbz=off`

(mesh not including gamma). However a little problem is that its threshold around 0.5eV is too high and slowly changing.

fig003: Alouanis' (from Arnaud) vs. 'Chi\_RegQbz = on' vs. 'Chi\_RegQbz = off'  
 As you see, the threshold of the Red line (20x20x20 Chi\_RegQbz=on) and Alouani's  
 are almost the same, but the red line is too oscillating at the low energy part.  
 On the other hand, 'Chi\_RegQbz = off' in Green broken line is not so satisfactory  
 at the low energy part.

fig.gas\_eps\_kconf.pdf shows the convergence behavior of epsilon for

## 2. $q \rightarrow 0$ convergence (this is related to whether Chi\_RegQbz=on or off).

If you use very small  $q$  like  $q=0.001$  in GaAs, it can cause a problem.

Use  $q=0.01$  or larger (maybe  $q=0.02$  or more is safer).

Very small  $q$  can give numerical error for high-energy region.

In fig004, we show the high energy tail part of  $\text{Im } \epsilon(\omega)$  for GaAs case.  
 At  $q=0.01$  (this means  $q = 2\pi/\text{alat} * (0.001)$ ), the imaginary part  
 is a little too large. Less than 80eV,  $q=0.02$  gives good results when compared with  
 other high  $q$  results, though it still has noise above 80eV.

In fig005, I showed the same results compared with Alouani's (his is up to 40eV).  
 Both gives rather good agreements. As you see,  $q=0.06$  or above might be necessary  
 to get reasonable convergence for high energy part above 40eV.

We have to be careful for this poor result in high energy part--- it may effect  
 low-energy  $\text{Re } \epsilon$  through KK relation. However this can be very small  
 enough.

In fig.gas\_eps\_qconv.jpg, we checked the convergence of  $\epsilon(\omega=0, q)$  for  $q \rightarrow 0$ .  
 As you see, it gives convergence, however,  $q=0.01$  is a little out of  
 curve---this should be because of the poor result in the high energy part.  
 so  $q=0.02$  or  $q=0.03$  is safer, and you can get  $\epsilon$  within 1 percent accuracy.

## 3. Including Core for dielectric constant is dangerous.

It can cause very poor results if you include core part in GWinput.

You need to include core just as valence (with local orbital).

In fig008, we showed core effects. It starts from  $\approx 16\text{eV}$   
 (this is core to conduction transition).

fig007 showed the check about the  $q$  point dependence---even with large  $q$ ,  
 it would not change.

These shows that the core excitation can have larger energy range.

This is in contrast to the valence case

(then the most of excitation is limited to less than 10eV).

We have to be careful for such high-energy excitation... The LMT0 basis might  
 be not so good for high energy.

## 4. basis set.

Use QpGcut\_psi  $\approx 3.0$  a.u. or so (as same as GW calculation).

In the case of epsPP\* mode,

QpGcut\_cou can be very small--- In our codes now,

$\text{ngc} \geq 1$  should be for all  $q$  vector shown in lqg4gw02 (output of echo 2|qg4gw).

[In principle, it should be only for the  $q$  vector for which we calculate epsilon.

But there is a technical poor result in our code---

(maybe) a problem here; the plane-wave part of the eigenfunction generated  
 in lmf2gw is not correctly passed to lmf2gw when  $\text{ngc}=0$ ].

-- eps\_lmfh: including LFC -----

To include eps with LFC, do eps\_lmfh.

But lcutmx=2 seems to be good enough to get 0.5 percent error (maybe better than this).

Test it 10x10x10 or so. (I need to repeat if necessary).

Further you can use smaller QpGcut\_cou like 2.2 or so,

with rather smaller product basis (up to p timed d, not including f).

Note: epsPP\_lmfh is designed to use good basis to calculate eps

without LFC. This is usually in agreement with what you obtained by eps\_lmfh;

however it can give slight difference when you use small product basis.

---Summary -----

So in conclusion, I think a best way to do is

1. set q=0.02 [q=2pi/alat(0 0 0.02)] or so for GaAs case.

If you want to check, do q=0.03 and q=0.06 also.

‘‘Chi\_RegQbz = off’’ is better for materials like GaAs with direct gap.

2. You can use small QpGcut\_cou but all ngc should be one or more.

3. As for the Product basis setting in epsPP\* scripts, only  
lcutmx and tolerance (this can be like 0.001 or so) are relevant.  
E.g. set lcutmx=4 or so.

4. Do nk=20 18 16 and take interpolation to determine eps(omega=0, q=0).

5. To get eps with LFC, set QpGcut\_cut as xxx, and set lcutmx=2 where  
(occupied sp) \timex (unoccupied spd) are included.

But correct EPS\*.nolfc.d is rather from epsPP\_lmfh script.

1	2	1	1	8	4
-2	1	2	1	9	5
-1	1	2	1	10	5
0	1	2	1	11	5

m is a magnetic quantum number, n is the degree of freedom which means 1 :  $\phi$ , 2 :  $\dot{\phi}$ , and 3 : local orbital. l is the orbital angular quantum number. The match of orbitals and m number is shown by **job.pdos** command. The following number is the number of atom. And the next is the numerating number. It corresponds to the number in GWinput which is the most left one in the initial conditions.

## 17 Overview of PMT-QSGW algorithm

The current `ecalj` is based on the PMT method [1, 11, 12]. With `ecalj`, we can do total energy calculation and atomic-position relaxations within LDA/GGA, and LDA+U. We can add spin-orbit coupling and so on (some limitations). An uniqueness is in the QSGW calculations, say, the PMT-QSGW method [2]. In addition, we can do linear responses, Wannier functions and so on in `ecalj`.

PMT-QSGW is an improved version of Ref.[13] within LMTO. We did new developments; some ideas are from papers Ref.[14] by Friedrich, Blügel, and Schindlmayr, and Ref.[15] by Freysoldt et al. In this Sec. 17, we try to explain some details along the line of Ref.[2].

### 17.1 Crystal structure, notations, and common data in code

We use unit `alat` (in a.u.) to represent length in the code. Thus, in cases, to convert quantities in the unit of a.u., we multiply `alat` to the quantities. For example, primitive cell (in a.u.) is given by `alat*plat(1:3,i),i=1,3)` (`plat=PLAT` in `ctrl` file). Here is some basic notations.

- Primitive vectors  $\mathbf{p}_i$  (in a.u.) are `alat*plat(1:3,i)`, where  $i=1,2,3$ . (see `LATTC`).  $\mathbf{q}_i=\mathbf{qlat}(1:3,i)$  is reciprocal unit vectors such that  $\text{sum}(\text{plat}(1:3,i),\text{qlat}(1:3,j))=\delta_{ij}$ .
- The centers of MT sites  $\{\mathbf{R}\}$  in the primitive cell is given by  $\{\mathbf{R}\}=\text{alat}*\text{bas}(1:3,\text{ibas}),\text{ibas}=1,\text{nbas}$  (we use `pos,natom` in cases instead of `bas,nbas`).  $\{\mathbf{R}\}$  is the position vector measured from a center of primitive cell.
- Thus the MT sites are specified by  $\mathbf{R} + \mathbf{T}$ , where  $\mathbf{T}$  specify centers of primitive cells.  $\mathbf{T}(n1,n2,n3) = n_1\mathbf{q}_1 + n_2\mathbf{q}_2 + n_3\mathbf{q}_3$ .
- In the followings, we use  $\mathbf{k}$  and  $\mathbf{q}$  (in cases, mixed up... sorry), both of which means vectors in the BZ.
- We specify MTs (atoms) in the cell (SPEC) in `ctrl` file. where the MTs (atoms) belonging to the same SPEC can be divided into some classes (CLASS) (we can use `lmchk` to check how they are classified).
- Note that we specify atoms in the cell (SPEC) in `ctrl` file. The same atoms belonging to the same SPEC can be classified into some classes (CLASS) (we can use `lmchk` to check how they are classified). `NBAS >= NSPEC >= NCLASS`
- `iclass(ibas)` is the id for class. The equivalent MT sites should have the same class id as `iclass(ibas1)=iclass(ibas2)`.  
(However, for the convenience of program developments, (historical reason), I assume `ibas=iclass(ibas)`; true class is `iclasst(ibas)`. This is used to find space group operations in call `mptauof`. A little complicated...)

---

Here is a common list of variables in `ecalj` code. Not all variables shown here.

```

alat: unit in a.u. This is in LATTC or (or call genallc_v3)
plat: primitive vector. this is in LATTC (or call genallc_v3)
qlat: reciprocal primitive vector
      \delta_ij= sum(plat(:,i)*qlat(:,j))
QpGcut_psi: cutoff to determine G vector for eigenfunction
            |q+G|< QpGcut_cou (in a.u.)
            CAUTION: in code, we usually represent q and G in the unit of
            2pi/alat, thus the cutoff is (in the program)
            2*pi/alat*sum((q+G)**2)< QpGcut_cou**2

QpGcut_cou: cutoff to to determine G vector for Coulmb matrix
            |q+G|< QpGcut_psi
symops (or symgg):
            space group, rotational part. This is in SYMOPS
            (or call genallc_v3)
nbas (or natom): number of MTs in the primitive cell.
```

```

corresponding to nbas, we usually use ibas for do loop
as "do ibas=1,nbas".
bas(1:3,1:natom) (or nbas): MT centers for R within the cell
    Cartesian coordinates in the unit of alat.
ng (or ngrp): number of space group operations.

tiat miat: given by subroutine mptauof. Space group operations.
    (mapping of atoms). (tiat(3,ibas,ig)
    See explanation it it.

Radial mesh: hbasfp0
    a,b, rofi,nr (or aa,bb, nrad).
    MT site radial data. Radial integrals are only in
    subroutine basnfp_v2 in hbasfp0.m.F.
    We assume r(ir)=b*(exp(aa*(ir-1)-1.), ir=1,nr
    rhoMT is read.

```

...xxxxx under construction xxxxx...

## 17.2 Representation of eigenfunctions

In the PMT method [16], the valence eigenfunctions for a given  $H^0$  are represented in the linear combinations of the Bloch-summed MTOs  $\chi_{\mathbf{RL}j}^{\mathbf{k}}(\mathbf{r})$  and the APWs  $\chi_{\mathbf{G}}^{\mathbf{k}}(\mathbf{r})$ ;

$$\Psi_{\mathbf{k}n}(\mathbf{r}) = \sum_{\mathbf{RL}j} z_{\mathbf{RL}j}^{\mathbf{k}n} \chi_{\mathbf{RL}j}^{\mathbf{k}}(\mathbf{r}) + \sum_{\mathbf{G}} z_{\mathbf{G}}^{\mathbf{k}n} \chi_{\mathbf{G}}^{\mathbf{k}}(\mathbf{r}), \quad (4)$$

where we use indexes of the wave vector  $\mathbf{k}$ , band index  $n$ , and reciprocal lattice vector  $\mathbf{G}$ . The MTOs in the primitive cell are specified by the index of MT site  $\mathbf{R}$ , angular momentum  $L = (l, m)$ , and  $j$  for radial functions. As for core eigenfunctions, we calculate them under the condition that they are restricted within MTs. Then we take into accounts the contributions of the cores to the exchange part defined in Eq. (22) in the following. But not to the correlation part. (caution: we now usally apply "core1 treatment" give in Ref.[3] for all cores. Rarely use core2).

### 17.2.1 MTO part

Within MTs, the Bloch sum of the MTO,  $\chi_{\mathbf{RL}j}^{\mathbf{k}}(\mathbf{r})$ , is expressed by a linear combination of atomic like orbitals  $A_{\mathbf{RL}j}(\mathbf{r}) \equiv \{\phi_{\mathbf{RL}j}(r), \dot{\phi}_{\mathbf{RL}j}(r), \phi_{\mathbf{RL}j}^z(r)\} \times Y_L$ . ( $\phi^z$  means local orbital). These radial functions are solutions of the radial Schrödinger equations (or their energy derivatives) within  $\mathbf{R}$ . The MTO basis is specified by smHankel functions which contains two parameters ( $E = -|\kappa|^2, R_{\text{sm}}$ ).

$A_{\mathbf{RL}j}(\mathbf{r})$  makes orthonormalized basis for each MT  $\mathbf{R}$ . Then the MTO including tail part can be written as

$$\begin{aligned} \chi_{\mathbf{RL}j}^{\mathbf{k}}(\mathbf{r}) &= \sum_{\mathbf{RL}j} C_{\mathbf{RL}j}^{\mathbf{k}} A_{\mathbf{RL}j}(\mathbf{r}) \quad \text{if } \mathbf{r} \in \text{any MT} \\ &= H_{\mathbf{RL}}^{\kappa, R_s, \mathbf{k}}(\mathbf{r}) \quad \text{otherwise,} \end{aligned} \quad (5)$$

where we use the Bloch sums,

$$A_{\mathbf{RL}j}^{\mathbf{k}}(\mathbf{r}) \equiv \sum_{\mathbf{T}} A_{\mathbf{RL}j}(\mathbf{r} - \mathbf{R} - \mathbf{T}) \exp(i\mathbf{kT}), \quad (6)$$

$$H^{\mathbf{k}s}(\mathbf{r}) \equiv \sum_{\mathbf{T}} H_s(\mathbf{r} - \mathbf{R} - \mathbf{T}) \exp(i\mathbf{kT}). \quad (7)$$

Here the smoothe Hankel functions  $H^{\mathbf{k}s}(\mathbf{r})$  are the envelope functions of MTOs.

### 17.2.2 APW part

The APW  $\chi_{\mathbf{G}}^{\mathbf{k}}(\mathbf{r})$  are given as a linear combination of atomic like orbitals  $A_{\mathbf{R}Lu}(\mathbf{r}) \equiv \{\phi_{\mathbf{R}Lu}(r)Y_L(\hat{\mathbf{r}}), \dot{\phi}_{\mathbf{R}Lu}(r)Y_L(\hat{\mathbf{r}})\}$  within MTs, and just the usual plane waves within the interstitial region. Here  $\phi_{\mathbf{R}Lu}(r)$  and  $\dot{\phi}_{\mathbf{R}Lu}(r)$  denote two solutions of the radial Schrödinger equations at an energy  $\mathbf{enu}$  for each  $l$  (an usual choice of  $\mathbf{enu}$  is the center of gravity of occupied PDOS).  $\dot{\phi}$  means energy derivatives (or something similar).  $u$  is the composite index to differentiate  $\phi$  and  $\dot{\phi}$ .  $\mathbf{R}$  is the index to specify MTs in the primitive cell. The APW basis is specified by  $s \equiv \mathbf{R}jL$ , where  $L \equiv (l, m)$  is the angular momentum index, and  $j$  is the additional index (principle quantum number or so).  $A_{\mathbf{R}Lu}(\mathbf{r})$  makes normalized-orthogonal basis in each MT  $\mathbf{R}$ . The APW can be written as

$$\begin{aligned}\chi^{\mathbf{k}+\mathbf{G}}(\mathbf{r}) &= \sum_{au} C_{au}^{\mathbf{k}+\mathbf{G}} A_{au}^{\mathbf{k}}(\mathbf{r}) \quad \text{if } \mathbf{r} \in \text{any MT} \\ &= \exp(i(\mathbf{k} + \mathbf{G})\mathbf{r}) \quad \text{otherwise,}\end{aligned}\tag{8}$$

where we use the Bloch sums,

$$A_{\mathbf{R}u}^{\mathbf{k}}(\mathbf{r}) \equiv \sum_{\mathbf{T}} A_{\mathbf{R}u}(\mathbf{r} - \mathbf{R} - \mathbf{T}) \exp(i\mathbf{k}\mathbf{T}),\tag{9}$$

The number of  $\mathbf{G}$  is limited by the condition  $|\mathbf{k} + \mathbf{G}| < \text{QpGcut.psi}$  (IPWpsi). The coefficients  $\alpha_{au}^{\mathbf{k}n}$  can be calculated as

$$\alpha_{au}^{\mathbf{k}n} = \sum_{\mathbf{G}} C_{au}^{\mathbf{k}+\mathbf{G}} z_n^{\mathbf{k}+\mathbf{G}}.\tag{10}$$

### 17.3 Re-expansion of eigenfunctions: CPHI and GEIG

To perform the  $GW$  calculation, we first have to prepare all eigenfunctions (and eigenvalues) for given setting of BZ mesh. Then the eigenfunctions are represented as follows; we re-expand  $\Psi_{\mathbf{k}n}(\mathbf{r})$  in Eq. (4) as the sum of the augmentation parts in MTs and the PW parts in the interstitial region.

$$\Psi_{\mathbf{k}n}(\mathbf{r}) = \sum_{\mathbf{R}u} \alpha_{\mathbf{R}u}^{\mathbf{k}n} \varphi_{\mathbf{R}u}^{\mathbf{k}}(\mathbf{r}) + \sum_{\mathbf{G}} \beta_{\mathbf{G}}^{\mathbf{k}n} P_{\mathbf{G}}^{\mathbf{k}}(\mathbf{r}),\tag{11}$$

where the interstitial plane wave (IPW) is defined as

$$P_{\mathbf{G}}^{\mathbf{k}}(\mathbf{r}) = \begin{cases} 0 & \text{if } \mathbf{r} \in \text{any MT} \\ \exp(i(\mathbf{k} + \mathbf{G}) \cdot \mathbf{r}) & \text{otherwise} \end{cases}\tag{12}$$

and  $\varphi_{\mathbf{R}u}^{\mathbf{k}}(\mathbf{r})$  are Bloch sums of the atomic functions  $\varphi_{Ru}(\mathbf{r})$  defined within the MT at  $R$ ,

$$\varphi_{\mathbf{R}u}^{\mathbf{k}}(\mathbf{r}) \equiv \sum_{\mathbf{T}} \varphi_{Ru}(\mathbf{r} - \mathbf{R} - \mathbf{T}) \exp(i\mathbf{k} \cdot \mathbf{T}).\tag{13}$$

$\mathbf{T}$  and  $\mathbf{G}$  are lattice translation vectors in real and reciprocal spaces, respectively. We explain how they can be represented in codes in Sec.??.

We expand the eigenfunctions as the sum of the augmentation parts in MTs and the PW parts in the interstitial region

$$\Psi_{\mathbf{k}n} = \sum_{\mathbf{R}u} \alpha_{\mathbf{R}u}^{\mathbf{k}n} \varphi_{\mathbf{R}u}^{\mathbf{k}}(\mathbf{r}) + \sum_{\mathbf{G}} \beta_{\mathbf{G}}^{\mathbf{k}n} P_{\mathbf{G}}^{\mathbf{k}}(\mathbf{r})\tag{14}$$

This is Eq.(17) in Ref.[2]. Here, Files CPHI contains the information of  $\alpha_{\mathbf{R}u}^{\mathbf{k}n}$  and GEIG contains  $\beta_{\mathbf{G}}^{\mathbf{k}n}$ . We use subroutines `readcphi` and `read eig` to read them; see `m_zeml.F` for example. (In future, we may start from better representation based on the 3 component formalism in Ref.[1].)

We need  $\Psi_{\mathbf{k}n}$  for given  $\mathbf{q}$  points (in this text, we mix up  $\mathbf{q}$  and  $\mathbf{k}$ ... Sorry.). Then  $P_{\mathbf{G}}^{\mathbf{k}}(\mathbf{r})$  is just specified by  $\mathbf{G}$ , which is generated by `qg4gw`.  $\varphi_{\mathbf{R}u}^{\mathbf{k}}(\mathbf{r})$  is specified by radial functions. It is contained in PHIVC read in `hbasfp0.m.F`. Number of radial functions are `ncore(ic)+nrad(ic)` (dependes on  $l, n, \sigma$ , but not on  $m$ ). For simplicity, maximum of  $l$  is fixed by LMXA in ctrl file. It must be the same for all MTs.

In the  $GW$  calculation of ecalj, important matrix elements related to the eigenfunction is only the matrix element as

$$\langle E_{\mu}^{\mathbf{q}} \Psi_{\mathbf{k}n} | \Psi_{\mathbf{q}+\mathbf{k}n'} \rangle,\tag{15}$$

, where  $E_\mu^q$  is the MPB (an unitary transformation of MPB). The information of eigenfunctions are used to calculate this matrix elements, which is read by `get_zmel`.

Coefficients of Eq. (11) (here is MTO part only) are calculated as

$$\alpha_{au}^{kn} = \sum_s C_{au}^{ks} z_s^{kn} \quad (16)$$

$$\beta_{\mathbf{G}}^{kn} = \sum_{\mathbf{G}'_s} \langle P_{\mathbf{G}}^{\mathbf{k}} | P_{\mathbf{G}'}^{\mathbf{k}} \rangle^{-1} \langle P_{\mathbf{G}'}^{\mathbf{k}} | H^{\mathbf{k}s} \rangle z_s^{kn}, \quad (17)$$

where the number of  $\mathbf{G}$  is limited by the condition  $|\mathbf{k} + \mathbf{G}| < \text{QpGcut\_psi}$ ;  $\mathbf{G}'$  is by  $|\mathbf{k} + \mathbf{G}'| < \text{QpGcutHakel}$ .

————— I think these are too old. Need check ————— `lm7K/fp/sugw.F` called from `lm7K/fp/bndfp.F` is a main part to generate this expansion. Important quantities in `lm7K/fp/sugw.F` are

- $z_s^{kn} = \text{zegf}(i, j)$ ;  $i=1, \text{ndimh}$ ;  $j=1, \text{ndimh}$  ( $i$  is for basis, and  $j$  is for band index.)
- $\alpha_{au}^{kn} = \text{cphi}$
- $\langle \phi_{Y_L} \text{ or } \dot{\phi}_{Y_L} | \chi^{\mathbf{k}s} \rangle = \text{phichi}$
- `phichi` is constructed from `phihd`, and `bmat`  $\times$  `phipkl`.
- `bmat` are generated in `hxp_b1`  $\in$  `augm.q`. It is the coefficients for the expansion of  $H^{\mathbf{k}s}(\mathbf{r})$  at the another MT center.

[`QpGcutHakel` is assumed as  $= 1.5 * \text{QpGcut\_psi}$  now. But it is not justified enough. You will be able to utilize more reasonable ones which was used in the LDA calculations.]

$\alpha_{au}^{kn}$  is calculated by the subroutine `getcoeffas` in `ng0.m.f`. The subroutine `matgg2`  $\in$  `mkppovl2`  $\in$  `pplmat2` in `pplmat.f` calculates  $\langle P_{\mathbf{G}}^{\mathbf{k}} | P_{\mathbf{G}'}^{\mathbf{k}} \rangle$  through

$$\begin{aligned} \langle P_{\mathbf{G}}^{\mathbf{k}} | P_{\mathbf{G}'}^{\mathbf{k}} \rangle &= \Omega \delta_{\mathbf{G}, \mathbf{G}'} - \sum_{a, L} \exp(i(\mathbf{G}' - \mathbf{G})\mathbf{R}_a) \times Y_L(\widehat{\mathbf{G}' - \mathbf{G}}) \\ &\times \int_a \exp(i(\mathbf{G}' - \mathbf{G})\mathbf{r}) d^3 r. \end{aligned} \quad (18)$$

$\langle P_{\mathbf{G}'}^{\mathbf{k}} | H^{\mathbf{k}s} \rangle$  is also calculated in `pplmat2` through the plane wave expansion of  $H^{\mathbf{k}s}$  (Eq.(9.4) of Ref.[17]). Then `pplmat2` gives the the coefficients  $\beta_{\mathbf{G}}^{kn}$ .

## 17.4 Overview of GW calculation

In the *GW* calculation, we need not only the basis set for eigenfunctions, but also the basis set for expanding the product of eigenfunctions. The basis is called the mixed product basis (MPB)  $\{M_I^{\mathbf{k}}(\mathbf{r})\}$  first introduced in Ref.[18] by Kotani. The MPB consists of the product basis (PB) within MTs [19] and the IPW in the interstitial region. Since  $\{M_I^{\mathbf{k}}(\mathbf{r})\}$  contains IPWs which are not orthogonal, we define dual for  $\{M_I^{\mathbf{k}}(\mathbf{r})\}$  as

$$|\tilde{M}_I^{\mathbf{k}}\rangle \equiv \sum_{I'} |M_{I'}^{\mathbf{k}}\rangle (O^{\mathbf{k}})_{I'I}^{-1}, \quad (19)$$

$$O_{I'I}^{\mathbf{k}} = \langle M_{I'}^{\mathbf{k}} | M_I^{\mathbf{k}} \rangle. \quad (20)$$

From  $v_{IJ}^{\mathbf{k}} = \langle M_I^{\mathbf{k}} | v | M_J^{\mathbf{k}} \rangle$ , we calculate the eigenfunction for the generalized eigenvalue problem defined by  $\sum_J (v_{IJ}^{\mathbf{k}} - v_\mu^{\mathbf{k}} O_{IJ}^{\mathbf{k}}) w_{\mu J}^{\mathbf{k}} = 0$ , where  $v_\mu(\mathbf{k})$  are the eigenvalues of the Coulomb interaction matrix. Then we have the Coulomb interaction represented by matrix elements as

$$v(\mathbf{k}) = \sum_\mu |E_\mu^{\mathbf{k}}\rangle v_\mu(\mathbf{k}) \langle E_\mu^{\mathbf{k}}|, \quad (21)$$

where we define a new MPB  $|E_\mu^{\mathbf{k}}(\mathbf{r})\rangle = \sum_J |M_J^{\mathbf{k}}\rangle w_{\mu J}^{\mathbf{k}}$ , which is orthonormal and is diagonal to the Coulomb interaction  $v(\mathbf{k})$ . For the all-electron full-potential *GW* approximation, Eq. (21) is introduced in Ref.[14]. This corresponds to the representation in the plane wave expansion

$v(\mathbf{k} + \mathbf{G}, \mathbf{k} + \mathbf{G}') = \frac{4\pi\delta_{\mathbf{G}\mathbf{G}'}}{|\mathbf{k} + \mathbf{G}|^2}$ .  $\mu = 1$  corresponds to the largest eigenvalue of  $v_\mu$ , and  $v_{\mu=1}$  is  $\sim \frac{4\pi e^2}{|\mathbf{k}|^2}$ , which is related to the divergent term discussed in Sec.21.

With the definition of  $\langle A|B \rangle = \int d^3r A^*(\mathbf{r})B(\mathbf{r})$ , the exchange part of  $\Sigma(\omega)$  is written as

$$\Sigma_{nm}^x(\mathbf{q}) = \langle \Psi_{\mathbf{q}n} | \Sigma_x | \Psi_{\mathbf{q}m} \rangle = - \sum_{\mathbf{k}} \sum_{n'}^{\text{BZ occ}} \langle \Psi_{\mathbf{q}n} | \Psi_{\mathbf{q}-\mathbf{k}n'} E_\mu^{\mathbf{k}} \rangle v_\mu(\mathbf{k}) \langle E_\mu^{\mathbf{k}} \Psi_{\mathbf{q}-\mathbf{k}n'} | \Psi_{\mathbf{q}m} \rangle. \quad (22)$$

The screened Coulomb interaction  $W(\omega)$  is calculated from

$$W = \epsilon^{-1} v = (1 - v\Pi)^{-1} v, \quad (23)$$

where the polarization function  $\Pi(\omega)$  is written as

$$\begin{aligned} \Pi_{\mu\nu}(\mathbf{q}, \omega) &= \sum_{\mathbf{k}} \sum_n^{\text{BZ occ}} \sum_{n'}^{\text{unocc}} \frac{\langle E_\mu^{\mathbf{q}} \Psi_{\mathbf{k}n} | \Psi_{\mathbf{q}+\mathbf{k}n'} \rangle \langle \Psi_{\mathbf{q}+\mathbf{k}n'} | \Psi_{\mathbf{k}n} E_\nu^{\mathbf{q}} \rangle}{\omega - (\varepsilon_{\mathbf{q}+\mathbf{k}n'} - \varepsilon_{\mathbf{k}n}) + i\delta} \\ &+ \sum_{\mathbf{k}} \sum_n^{\text{BZ unocc}} \sum_{n'}^{\text{occ}} \frac{\langle E_\mu^{\mathbf{q}} \Psi_{\mathbf{k}n} | \Psi_{\mathbf{q}+\mathbf{k}n'} \rangle \langle \Psi_{\mathbf{q}+\mathbf{k}n'} | \Psi_{\mathbf{k}n} E_\nu^{\mathbf{q}} \rangle}{-\omega - (\varepsilon_{\mathbf{k}n} - \varepsilon_{\mathbf{q}+\mathbf{k}n'}) + i\delta}. \end{aligned} \quad (24)$$

When time-reversal symmetry is assumed,  $\Pi(\omega)$  can be simplified to read

$$\begin{aligned} \Pi_{\mu\nu}(\mathbf{q}, \omega) &= \sum_{\mathbf{k}} \sum_n^{\text{BZ occ}} \sum_{n'}^{\text{unocc}} \langle E_\mu^{\mathbf{q}} \Psi_{\mathbf{k}n} | \Psi_{\mathbf{q}+\mathbf{k}n'} \rangle \langle \Psi_{\mathbf{q}+\mathbf{k}n'} | \Psi_{\mathbf{k}n} E_\nu^{\mathbf{q}} \rangle \\ &\times \left( \frac{1}{\omega - \varepsilon_{\mathbf{q}+\mathbf{k}n'} + \varepsilon_{\mathbf{k}n} + i\delta} - \frac{1}{\omega + \varepsilon_{\mathbf{q}+\mathbf{k}n'} - \varepsilon_{\mathbf{k}n} - i\delta} \right). \end{aligned} \quad (25)$$

To evaluate Eq. (24) or Eq. (25), we first accumulate the imaginary parts (anti-Hermitian part) of  $\Pi_{\mu\nu}(\mathbf{q}, \omega)$  along bins of histograms on the real axis  $\omega$  by the tetrahedron technique [20], and then determine the real part via the Hilbert transformation. The bins are dense near the Fermi energy and coarser at higher energy as described in Ref.[13]. This procedure is not only more efficient but also safer than the methods of calculating the real part directly. We also use the extended irreducible zone (EIBZ) symmetrization procedure described in Ref.[14].

The correlation part of the screened Coulomb interaction  $W^c(\omega) = W(\omega) - v$ , which is calculated from  $v$  and  $\Pi(\omega)$ , is given as

$$W^c(\mathbf{k}, \omega) = \sum_{\mu\nu} |E_\mu^{\mathbf{k}} \rangle W_{\mu\nu}^c(\mathbf{k}, \omega) \langle E_\mu^{\mathbf{k}}|. \quad (26)$$

With this  $W^c(\mathbf{k}, \omega)$ , we have the correlation part of the self-energy as

$$\Sigma_{n,n'}^c(\mathbf{q}, \omega) = \sum_{\mathbf{k}, m} \int_{-\infty}^{\infty} d\omega' \sum_{\mu, \nu} \frac{\langle \Psi_{\mathbf{q}n} | \Psi_{\mathbf{q}-\mathbf{k}m} E_\mu^{\mathbf{k}} \rangle W_{\mu\nu}^c(\mathbf{k}, \omega') \langle E_\nu^{\mathbf{k}} \Psi_{\mathbf{q}-\mathbf{k}m} | \Psi_{\mathbf{q}n'} \rangle e^{-i\delta\omega'}}{\omega - \omega' - \varepsilon_{\mathbf{q}-\mathbf{k}m} \pm i\delta}. \quad (27)$$

Here, we use  $-i\delta$  for occupied states of  $\mathbf{q}-\mathbf{k}m$ , and  $+i\delta$  for unoccupied states. In QSGW, we have to calculate the Hermitian part of  $\Sigma_{nn'}(\mathbf{q}, \varepsilon_{\mathbf{q}n})$ , to obtain  $V_{\mathbf{q}}^{\text{xc}}$  using Eq. (??).

There are two key points to handle the  $GW$  procedure given above. The first key point, given in Sec.21, is the improved offset- $\Gamma$  method, which treats the divergence of  $W^c(\mathbf{k} \rightarrow 0, \omega)$  in Eq. (27). For this purpose, we define the non-divergent effective interaction  $\bar{W}^c(\mathbf{k} = 0, \omega)$  instead of  $W^c(\mathbf{k} = 0, \omega)$ . Then we can take a simple discrete sum for both expressions of Eqs.(22) and (27).

The second point in Sec.25 is how to perform an interpolation to give  $V_{\mathbf{q}}^{\text{xc}}$  at any  $\mathbf{q}$  in the whole BZ, from  $V_{\mathbf{q}}^{\text{xc}}$  calculated only at limited numbers of  $\mathbf{q}$  points. This is required in the offset- $\Gamma$  method shown in Sec.21, that is, we have to calculate eigenfunctions at some  $\mathbf{q}$  points near  $\mathbf{q} = 0$ . For the interpolation, we expand the static nonlocal potential  $V^{\text{xc}}$  in Eq. (??) in highly localized MTOs in real space. Thus such MTOs are used for two purposes: one as the basis of the eigenfunctions; and two as the basis of expanding  $V^{\text{xc}}$ . The interpolation procedure of  $V_{\mathbf{k}}^{\text{xc}}(\mathbf{r}, \mathbf{r}')$  becomes stabler and simpler than the complicated interpolation procedure in Ref.[13]. This is because we now use highly localized MTOs. In the planewave-based QSGW method by Hamann and Vanderbilt [21], they expand  $V^{\text{xc}}$  in the maximally localized Wannier functions instead of MTOs.

In practical implementation, the LDA or GGA exchange-correlation potential  $V_{\text{LDA}}^{\text{xc}}$  is used to perform efficient numerical calculations. That is, it is used in order to generate core

eigenfunctions as well as radial functions within MTs (in this paper, we use the subscript LDA even when we use GGA. “LDA/GGA” means LDA or GGA). The difference  $V^{\text{xc}} - V_{\text{LDA}}^{\text{xc}}$  is used for the interpolation in the BZ (explained in Sec.25), because this difference is numerically small as long as  $V_{\text{LDA}}^{\text{xc}}$  roughly gives an approximation to  $V^{\text{xc}}$ . This procedure utilizing  $V_{\text{LDA}}^{\text{xc}}$  to perform efficient numerical calculations give a very weak dependence to the final numerical results in practice as seen in Sec.??, although the results formally does not depend on the LDA/GGA exchange-correlation functions.

## 18 q and G vector generation. qg4gw

...xxxxx under construction xxxxx...

To see the theory, read Section 3.2 in in [2]  $\mathbf{k}$  points are the regular mesh points used for the integration in the BZ. Regular mesh points are given as

$$\mathbf{k}_{i_1, i_2, i_3} = (i_1/N_1) * \mathbf{P}_1 + (i_2/N_2) * \mathbf{P}_2 + (i_3/N_3) * \mathbf{P}_3 \quad (28)$$

, where  $\mathbf{P}_i$  is the primitive vector  $\frac{2\pi}{\text{alat}} \times$  Quantities  $f(\mathbf{k})$  (periodic in BZ) can be integrated just as a sum on the regular mesh points. However, when  $f(\mathbf{k} = 0)$  is divergent, we have careful treatments.

`qlat(:,il)`, where `qlat= $\mathbf{Q}_i$`  is the reciprocal vectors. See Sec.3.2 .

`mkqg.F` is the main part of **qg4gw** (`fpgw/main/qg4gw.F`). `iq0pin` is the job control of `mkqg`. `iq0pin=101` is only for backward compatibility. The purpose is generates required  $\mathbf{q}$  and  $\mathbf{G}$  vectors. Not only regular mesh points, or  $\mathbf{q}$  along symmetry lines, but also offset Gamma points.

`iq0pin=1`: normal mode. Generate  $\mathbf{q}$  and  $\mathbf{G}$  for regular mesh point and Q0P points (offset Gamma points).

`iq0pin`: input to `qg4gw`

### 18.0.1 Make $\mathbf{G}$ vectors: `getgv2`

To get  $\mathbf{G}$  vectors, we use an algorithm in `fpgw/getgv2.F`, whose head is

```
subroutine getgv2(alat,plat,qlat,q, QpGcut,job,
o              ng, ngvec)
!! == Set up a list of recip vectors within cutoff |Q+G| < QpGcut a.u. ==
!! job==1 -> return ng (number of G ) and imx(as ngvec(1,1));mar2012takao add imx.
!! job==2 -> return ng and ngvec
!! True G is given as
!!   G(1:3,1:ng) = 2*pi/alat * matmul(qlat * ngvec(1:3,1:ng))
!! NOTE: we need some geometorial consideration for this routine.
!!   Consiser ellipsoid. Takao need to give more detailed explanation...
!! -----
```

We can use this to get  $\{\mathbf{G}\}$  for given  $\mathbf{q}$ . The algorism of `getgv2` is a little complicated. We first gives the upper and lower limits  $n1\text{max} \leq n_1 \leq n1\text{min}$ , where  $\mathbf{G} = n_1\mathbf{Q}_1 + n_2\mathbf{Q}_2 + n_3\mathbf{Q}_3$ ,  $n_2$  and  $n_3$  as well.

...xxxxx under construction xxxxx...

### Algorithm of `getgv2`.

Let us consider the three dimensional space of  $\mathbf{x} = \mathbf{q} + \mathbf{G}$ . For given  $\mathbf{q}$ , allowed  $\mathbf{G}$  make a set of regular mesh points  $\{\mathbf{q} + \mathbf{G}\}$ . The purpose of `getgv2` is picking up only mesh points satisfying  $|\mathbf{q} + \mathbf{G}| < Q_{\text{pGcut}}$  among these mesh points.

At first, we can calculate allowed range of  $n_1$  for given maximum of  $|\mathbf{q} + \mathbf{G}| (=Q_{\text{pGcut}})$ . Note  $|\mathbf{x}| = |\mathbf{q} + \mathbf{G}| = Q_{\text{pGcut}}$  gives a sphere; we have to pick up mesh points within the sphere. When we specify  $n_1$ , we have a plane (allowing  $n_2, n_3$  can take any values). The range is determined by the condition that the sphere  $|\mathbf{q} + \mathbf{G}| = Q_{\text{pGcut}}$  cross the plane specified by  $n_1$  (exactly speaking, such  $n_1$  is real number). The vector normal to the plane is the external product  $Q_2 \times Q_3$ .

After we get the range of  $n_1$ , as well as  $n_2, n_3$ , we simply test whether  $\mathbf{q} + \mathbf{G}$  for  $(n_1, n_2, n_3)$  is allowed or not.

### 18.0.2 Make $G$ vectors: `shortn3`

Find shortest vector in modulo of  $\{Q_i\}$ . That is, pull back  $\mathbf{q}$  in the 1st BZ. Caution; it can be not unique when  $\mathbf{q}$  is on the BZ boundary; then we need to know all  $\mathbf{q}$  and degeneracy.

## 19 Mixed Product basis

The mixed product basis consists of two types of basis sets, that is the product basis and the IPW:  $\{M_I^{\mathbf{k}}(\mathbf{r})\} \equiv \{P_{\mathbf{G}}^{\mathbf{k}}(\mathbf{r}), B_{\mathbf{R}\mu}^{\mathbf{k}}(\mathbf{r})\}$ , where the index  $I \equiv \{\mathbf{G}, \mathbf{R}\mu\}$  classifies the members of the basis. The PB  $B_{\mathbf{R}\mu}^{\mathbf{k}}(\mathbf{r})$  is defined as

$$B_{\mathbf{R}\mu}^{\mathbf{k}}(\mathbf{r}) = \sum_{\mathbf{T}} B_{\mathbf{R}\mu}(\mathbf{r} - \mathbf{R} - \mathbf{T}) e^{i\mathbf{k} \cdot \mathbf{T}}, \quad (29)$$

where  $B_{\mathbf{R}\mu}(\mathbf{r})$  is made from the products of radial functions.  $B_{\mathbf{R}\mu}(\mathbf{r})$  is real and zero for outside of MT,  $|\mathbf{r}| > R$  (See Sec.19.1). We set up  $\{B_{\mathbf{R}\mu}(\mathbf{r})\}$  so that they are orthonormalized;

$$\int_{|\mathbf{r}| < R} B_{\mathbf{R}\mu}(\mathbf{r}) B_{\mathbf{R}\mu'}(\mathbf{r}) d^3r = \delta_{\mu\mu'}. \quad (30)$$

In addition, it is trivial that  $\{B_{\mathbf{R}\mu}(\mathbf{r})\}$  and  $\{P_{\mathbf{G}}^{\mathbf{k}}(\mathbf{r})\}$  are orthogonal. Thus only the elements of overlap matrix is

$$O_{IJ}^{\mathbf{k}} = \int_{\Omega} \{M_I^{\mathbf{k}}(\mathbf{r})\}^* M_J^{\mathbf{k}}(\mathbf{r}) d^3r, \quad (31)$$

because  $\{P_{\mathbf{G}}^{\mathbf{k}}(\mathbf{r})\}$  are not orthogonal. Thus it is convenient to define the dual of  $M_I^{\mathbf{k}}(\mathbf{r})$  as  $\tilde{M}_I^{\mathbf{k}}(\mathbf{r})$  in the manner of Eq. (20).

Functions made from the product of eigenfunctions can be virtually completely expanded in the basis of  $M_I^{\mathbf{k}}(\mathbf{r})$  in this manner;

$$\begin{cases} F^{\mathbf{k}}(\mathbf{r}) = \sum_I M_I^{\mathbf{k}}(\mathbf{r}) F_I(\mathbf{k}) \\ F_I(\mathbf{k}) = \int_{\Omega} \{\tilde{M}_I^{\mathbf{k}}(\mathbf{r})\}^* F^{\mathbf{k}}(\mathbf{r}) d^3r. \end{cases} \quad (32)$$

### 19.1 Product basis (`hbasfp0`)

We denote the radial function of atom  $a$  as

$$u_{apl\sigma}(r) = r\phi_{apl\sigma}(r), \quad (33)$$

where the index  $p$  takes 1 for  $\phi$ , 2 for  $\dot{\phi}$ , 3 for local orbital as well. We do not allow  $m$  dependence ( $m$  is  $m$  of  $L = (l, m)$ .) for the radial functions. In addition,  $p$  can take indexes to specify core functions: we combine core and valence functions (these are stored in PHIVC, which read in `hbasfp0.m.F`). Here is a part of copy to read PHIVC in `hvcfp0.m.F`

```

ifphi = iopen('PHIVC', 0,-1,0)! augmentation wave and core
read(ifphi) nbas, nradmx, ncoremx
allocate( ncindx(ncoremx,nbas),
&         lcindx(ncoremx,nbas),
&         nrad(nbas), nindx_r(1:nradmx,1:nbas),
&         lindx_r(1:nradmx,1:nbas),

```

```

&      aa(nbas),bb(nbas),zz(nbas), rr(nrx,nbas), nrofi(nbas) ,
&      phitoto(nrx,0:nl-1,nn,nbas,nsp),
&      phitotr(nrx,0:nl-1,nn,nbas,nsp),
&      nc_max(0:nl-1,nbas),ncore(nbas) )
read(ifphi) nrad(1:nbas)
read(ifphi) nindx_r(1:nradmx,1:nbas),lindx_r(1:nradmx,1:nbas)
nc_max=0
do ibas=1,nbas
  write(6,*)' --- read PHIVC of ibas=',ibas
  ic = ibas
  read(ifphi) ncore(ic), ncoremx !core
  read(ifphi) ncindx(1:ncoremx,ibas),lcindx(1:ncoremx,ibas) !core
  read(ifphi) icx,zz(ic),nrofi(ic),aa(ic),bb(ic)
  if(ic/=icx) then
    write(6,*) 'ic icx=',ic,icx
    call rx( 'hbasfp0: ic/=icx')
  endif
  read(ifphi) rr(1:nrofi(ic),ic)
  do isp = 1, nsp
    write(6,*)'--- isp nrad ncore(ic)=',isp, nrad(ic),ncore(ic)
    do icore = 1, ncore(ic)
      l = lcindx(icore,ic)
      n = ncindx(icore,ic)
      read(ifphi) phitoto(1:nrofi(ic),l,n, ic,isp)!core orthogonal
      phitotr(1:nrofi(ic),l,n, ic,isp)= !we set core raw= core orthogonal
&      phitoto(1:nrofi(ic),l,n, ic,isp)
      if(n>nc_max(l,ic)) nc_max(l,ic)=n
    enddo
    do irad = 1, nrad(ic)
      l = lindx_r (irad,ic)
      n = nindx_r (irad,ic) + nc_max(l,ic)
      read(ifphi) phitoto(1:nrofi(ic),l,n, ic,isp) !valence orthogonal
      read(ifphi) phitotr(1:nrofi(ic),l,n, ic,isp) !valence raw
    enddo
  enddo
enddo
enddo

```

[note: The orthonormalized radial functions  $u_{apl\sigma}(r)$  are stored in **phitoto**; we also have the un-orthonormalized ones in **phitotr**.]

Note that the *true* radial function is  $\phi_{apl\sigma}(r) = u_{apl\sigma}(r)/r$ . Normalization is  $1 = \int_0^{R_a} \{u_{apl\sigma}(r)\}^2 dr = \int_0^{R_a} \{\phi_{apl\sigma}(r)\}^2 r^2 dr$ . The function  $u_{apl\sigma}(r)$  is stored in **phitot**.

When producing the product functions, we use spin-averaged function **phiav** given as

$$u_{apl}(r) = \frac{1}{N_{\text{spin}}} \sum_{\sigma} u_{apl\sigma}(r). \quad (34)$$

(See subroutine **basnfp\_v2**). From them, we make the product functions **rprod**

$$\tilde{b}_{al\nu}(r) = \frac{1}{r} u_{apl}(r) u_{ap'l'}(r) = r \phi_{apl}(r) \phi_{ap'l'}(r), \quad (35)$$

where the index  $l$  runs  $|l - l'| \leq l \leq |l + l'|$ ;  $\nu$  is the index of the combination  $(p, p')$ . Note the *true* product functions are given as

$$\tilde{B}_{al\nu}(r) = \frac{1}{r} \tilde{b}_{al\nu}(r). \quad (36)$$

This relation is as same as  $\phi_{apl}(r) = u_{apl}(r)/r$ .

Then we calculate the overlap matrix **ovmt**,

$$O_{\nu_1\nu_2} = \int_0^{R_a} \tilde{B}_{al\nu_1}(r) \tilde{B}_{al\nu_2}(r) r^2 dr = \int_0^{R_a} \phi_{ap_1l_1}(r) \phi_{ap'_1l'_1}(r) \phi_{ap_2l_2}(r) \phi_{ap'_2l'_2}(r) r^2 dr \quad (37)$$

and solve the eigenvalue problem of the overlap matrix,  $Oz_{\nu} = \epsilon_{\nu} z_{\nu}$ , by call **rs(..)**. (See **basnfp\_v2**.)

After neglecting eigenvectors  $z_{\nu}$  with eigenvalues  $\epsilon_{\nu} < \text{tolerance} \sim 10^{-4}$  (given in **GWinput**), we finally have the optimal product functions as the linear combinations of the product functions as

$$b_{al\nu}(r) = \frac{1}{\sqrt{\epsilon_{\nu}}} \sum_{\nu'} \tilde{b}_{al\nu'}(r) z_{\nu'\nu}, \quad (38)$$

which are stored in **rprodx** and written into **BASFP\*** and used in the successive Coulomb matrix routine **hvcfp0.m.f**. Of course, *true* product function is  $B_{al\nu}(r) = b_{al\nu}(r)/r$ .

We check the normalization of the optimal product function in standard output (See **lbasC** and **lbas** when you did **gw\_lmf**):

```

...
Use rs diagonalization for real symmetric
Diag ibx ovv= 1 0.99999999999999930D+00 eb= 0.2716113799D-01 nod= 2
Diag ibx ovv= 2 0.99999999999999980D+00 eb= 0.4993303381D-01 nod= 3
Diag ibx ovv= 3 0.1000000000000001D+01 eb= 0.1467546915D+00 nod= 3
Diag ibx ovv= 4 0.9999999999999996D+00 eb= 0.4415639258D+01 nod= 0

```

...

In **basnfp**, we calculate all the required radial integrations  $\langle \phi\phi B \rangle = \text{ppbrd}$ ;

$$\langle \phi\phi B \rangle = \int_0^{R_a} \phi_{ap_1l_1}(r) \phi_{ap_2l_2}(r) B_{al\nu}(r) r^2 dr = \int_0^{R_a} \frac{1}{r} u_{ap_1l_1}(r) u_{ap_2l_2}(r) b_{al\nu}(r) dr, \quad (39)$$

which are stored into **PPBRD\***. At call **rdpp**(... in **hx0fp0.m.f** **hxfp0.m.f**, we allocate and read **ppbrd**.

In addition, we read the "rotated Clebsh-Gordon coefficient"  $C(L, L_1, L_2, g)$  **cgr**(**lm**, **lm1**, **lm2**, **ng**), where  $g$  is the index for space group coefficient (rotated by point group symmetries).

## 20 The Coulomb matrix (**hvccfp0.m.F**)

We have to calculate  $v_{IJ}^{\mathbf{k}} = \langle M_I^{\mathbf{k}} | v | M_J^{\mathbf{k}} \rangle$ , which appears right after Eq. (20). Our **hvccfp0.m.F** can handle the case  $\frac{\exp(-|\kappa||\mathbf{r}_1 - \mathbf{r}_2|)}{|\mathbf{r}_1 - \mathbf{r}_2|}$ . The default is the bare Coulomb interaction, that is,  $\kappa = 0$ . The energy variable  $E$  is given by  $E = \kappa^2$ , where imaginary part of  $\kappa$  is defined to be positive for negative  $E$ . This  $E = \text{eee} = \text{screenfac}()$  in **hvccfp0.m.F**. For example, we can set  $|\kappa| = 0.1$  (a.u.) by a line "**TFscreen 0.1**" in **GWinput** if necessary. Look for **TFscreen** in **switches.F**.

The MPB is made of **IPWcou** ( $|\mathbf{q} + \mathbf{G}| < \text{qpGcut\_cou}$ ) and **PB**, that is,  $\{M_J^{\mathbf{k}}\} = \{P_{\mathbf{G}}^{\mathbf{k}}(\mathbf{r}), B_{\mathbf{RL}\mu}^{\mathbf{k}}(\mathbf{r})\}$ . For given  $\mathbf{k}$  (not explicitly shown in cases for simplicity), **IPWcou** is specified just by the  $\mathbf{G}$  vector. **PB** is generated in the manner of Sec.19. **PB** can be specified just by the radial functions for each  $l$  (because we have neither  $m$  nor spin dependence). For  $GW$  calculation, we need the Coulomb matrix elements  $\langle B|v|B \rangle$ ,  $\langle B|v|P_{\mathbf{G}} \rangle$ , and  $\langle B|v|P \rangle$ . **hvccfp0.m.F**  $\rightarrow$  **vcoulq\_4** handles these calculations.

### 20.1 Spherical Bessel and related functions

We use a notation such that  $X_L(\mathbf{r}) = X_l(r)Y_L(\hat{r})$ ; note that their radial part is dependent only on  $l$ . The ordinary definition of  $L$ -dependent spherical Bessel functions  $J_L(E, \mathbf{r})$ ,  $H_L(E, \mathbf{r})$  are

$$\begin{aligned} J_L(E, \mathbf{r}) &= j_l(i|\kappa|r)Y_L(\hat{r}) \text{ for } E < 0, = j_l(\kappa r)Y_L(\hat{r}) \text{ for } E > 0 \\ H_L(E, \mathbf{r}) &= h_l(i|\kappa|r)Y_L(\hat{r}) \text{ for } E < 0, \end{aligned} \quad (40)$$

where  $j_l(z)$  and  $h_l(z)$  are usual spherical Bessel and Hankel functions which behaves

$$\begin{aligned} j_l(z) &\sim \frac{z^l}{(2l+1)!!} \\ h_l(z) &\sim \frac{-i(2l-1)!!}{z^{l+1}}. \end{aligned} \quad (41)$$

For convenience, we define the **Methfessel's Bessel functions (convension)**  $\bar{J}_L = \bar{J}_l Y_L$  and  $\bar{H}_L = \bar{H}_l Y_L$ , where

$$\begin{aligned} \bar{J}_l(E, \mathbf{r}) &= j_l(i|\kappa|r)/(i|\kappa|)^l \\ \bar{H}_l(E, \mathbf{r}) &= h_l(i|\kappa|r)i(i|\kappa|)^{l+1}. \end{aligned} \quad (42)$$

(memo: for example,  $7!! = 7 \cdot 5 \cdot 3 \cdot 1$ ; **function fac2m(i)**). These are real functions for  $E \leq 0$ . See note for **genjh** in **mkjp.F**. At  $E = 0$ , this is reduced to be

$$\bar{J}_l(E = 0, \mathbf{r}) = r^l / (2l+1)!!, \quad (43)$$

$$\bar{H}_l(E = 0, \mathbf{r}) = r^{-l-1} (2l-1)!!. \quad (44)$$

Our default setting is with very small negative  $E$  to avoid numerical trouble in cases (see default **screenfac** in **switch.F**).

The source codes to define `bessl` is a little confusing because of some conventions are mixed up...(note at the beginning of `besslr.F`). We have `call bessl(ex2, lx, phi(0:lx), psi(0:lx))` in `mkjp.F` and so on. For given `ex2 = E × x2`, this return spherical Bessel functions  $j_l(\kappa x)$  as  $j_l(\kappa x) = \text{phi}(1)x^l$ .  $\kappa^2 = E$  (for negative  $E$ , imaginary part of  $\kappa$  is positive). `lx` is the upper limit of  $l$ . This is defined in `bessl(ex2, lmax, phi, psi)` in `besslr.F` (it calls `besslr` with `loka=F`). It gives

$$\left. \begin{aligned} j_l(i|\kappa|r) &= \text{phi}(1)r^l \\ h_l(i|\kappa|r) &= \text{psi}(1)\frac{1}{r^{l+1}} \end{aligned} \right\} \quad \text{for } E < 0, \kappa = i|\kappa|, |\kappa| = \sqrt{|E|} \quad (45)$$

$$\left. \begin{aligned} j_l(\kappa r) &= \text{phi}(1)r^l \\ n_l(\kappa r) &= \text{psi}(1)\frac{1}{r^{l+1}} \end{aligned} \right\} \quad \text{for } E > 0, \kappa = \sqrt{E} \quad (46)$$

for  $0 \leq l \leq \text{lmax}$ . (This means  $\text{phi} = 1/(2l+1)!!$  and  $\text{psi} = (2l-1)!!$  at  $E \rightarrow 0$ ). Here  $n_l(r)$  is the spherical Neumann functions.

That is, `psi` is for Hankel function for negative  $E$ , and for Neumann function for positive  $E$ . See `hansmr.F`, for example. `psi` is not used so often. We have `lm7K/subs/besslr.F`, it is similar. We may need to simplify our treatment of bessel functions in future...

**electron-phonon coupling in MPB** To calculate derivative for electron-phonon (EP) coupling, we need

$$\frac{\partial}{\partial \mathbf{r}_i} (\bar{J}_l(E, \mathbf{r}) Y_L(\hat{r})) \big|_{\mathbf{r}=0} = 1/3, \quad (47)$$

only cases for  $L = 1$ , zero for other  $L$ . For real spherical harmonics, cases are:  $i = y$  and  $L = (1, -1)$ ;  $i = z$  and  $L = (1, 0)$ ;  $i = x$  and  $L = (1, 1)$ . Because we use MPB, it is necessary to evaluate the bare matrix element of the Coulomb interaction between nucleus and  $\langle B \rangle$  as

$$\langle B | \frac{\partial v(\mathbf{r} - \mathbf{R})}{\partial \mathbf{R}_i} \rangle \quad (48)$$

## 20.2 Green function

(Readers can skip this subsection). We explain the free-space Green's function  $G(\mathbf{r} - \mathbf{r}', E)$  here. Let us start from  $G(\mathbf{r} - \mathbf{r}', E)$ , which satisfies

$$(E + i\delta + \nabla^2)G(\mathbf{r} - \mathbf{r}', E) = \delta(\mathbf{r} - \mathbf{r}'). \quad (49)$$

( $+i\delta$  is to specify the boundary condition along time axis. This pick up the retarded Green's function). Roughly speaking, this is  $(\omega - H)G = 1$ . Its Fourier transform is easily written as  $G(\mathbf{k}, E) = 1/(E - |\mathbf{k}|^2 + i\delta)$ . We apply back Fourier transformation to this, and get  $G(\mathbf{r} - \mathbf{r}', E)$ . It is

$$G(\mathbf{r} - \mathbf{r}', E) = -\frac{1}{4\pi} \frac{e^{i\kappa|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r} - \mathbf{r}'|}, \quad (50)$$

where  $\kappa \equiv \sqrt{E}$ ; Imaginary part of  $\kappa$  is positive for  $E < 0$ , that is,  $\kappa = i|\kappa| = i\sqrt{-E}$  for negative  $E$ . Eq. (50) is nothing but the solution of Helmholtz differential equation; it reduces to the usual Poisson equation at  $E = 0$ . For  $E < 0$ , we have Thomas-Fermi type function; the numerator of Eq. (50) is  $\exp(i\kappa|\mathbf{r} - \mathbf{r}'|) = \exp(-|\kappa||\mathbf{r} - \mathbf{r}'|)$ .

## 20.3 Used formulas

$$\frac{1}{4\pi} \frac{1}{|\mathbf{r} - \mathbf{r}'|} = \sum_K \frac{r_{<}^k}{r_{>}^{k+1}} \frac{1}{2k+1} Y_K^*(\hat{\mathbf{r}}) Y_K(\hat{\mathbf{r}}) \quad (51)$$

See Appendix A in Ref.[23]. This is generalized to be

$$\frac{1}{4\pi} \frac{e^{-|\kappa||\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r} - \mathbf{r}'|} = \sum_L \bar{J}_L(E, r_{<}) \bar{H}_L(E, r_{>}), \quad (52)$$

The definition of  $\bar{J}$  is in Eq.42. Here  $E = -|\kappa|^2 < 0$ ; then Im part of  $\kappa$  is positive.

$$\exp(i\mathbf{k}\mathbf{r}) = 4\pi \sum_L i^l j_l(|\mathbf{k}|r) Y_L^*(\hat{\mathbf{k}}) Y_L(\hat{\mathbf{r}}) \quad (53)$$

$$\frac{2l+1}{4\pi} P_l(\cos \Theta) = \sum_m Y_L^*(\hat{\mathbf{r}}_1) Y_L(\hat{\mathbf{r}}_2) \quad [\cos \Theta = \hat{\mathbf{r}}_1 \cdot \hat{\mathbf{r}}_2]. \quad (54)$$

$$\begin{aligned} \langle P_{\mathbf{G}}^{\mathbf{k}} | P_{\mathbf{G}'}^{\mathbf{k}} \rangle &= \Omega \delta_{\mathbf{G}, \mathbf{G}'} - \sum_{a,L} \exp(i(\mathbf{G} - \mathbf{G}')\mathbf{R}_a) \times Y_L(\widehat{\mathbf{k} + \mathbf{G}'}) Y_L(\widehat{\mathbf{k} + \mathbf{G}}) \\ &\quad \times \int_0^{R_a} j_l(|\mathbf{k} + \mathbf{G}|r) j_l(|\mathbf{k} + \mathbf{G}'|r) 4\pi^2 r^2 dr, \end{aligned} \quad (55)$$

## 20.4 Hankel function and Structure constant

We can expand  $v(\mathbf{r}, \mathbf{r}') = \frac{e^{-|\kappa||\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|}$  in the one-center expansion Eq. (52).

For the Hankel function in Eq. (52), we use the off-center expansion theorem of the Hankel function Eq. (56), that is, a Hankel whose center is at  $\mathbf{X} \equiv \mathbf{R} + \mathbf{T}$ ,  $H_L(\mathbf{r} - \mathbf{X})$ , can be expanded in the Bessel functions whose center is at  $\mathbf{X}'$ ;

$$\bar{H}_L(E, \mathbf{r} - \mathbf{X}) = \sum_{L'} \bar{J}_{L'}(E, \mathbf{r} - \mathbf{X}') S_{\mathbf{X}'L', \mathbf{X}L}, \quad (56)$$

where the Hankel function for negative energy  $E$ . Here  $E$ -dependence of  $S_{\mathbf{X}'L', \mathbf{X}L'}$  is not explicitly shown. Note the difference between  $\bar{J}_L$  and  $J_L$  ( $\bar{H}_L$ , as well).

Thus, for  $(\mathbf{R}', \mathbf{T}') \neq (\mathbf{R}, \mathbf{T})$ , we have two-center expansion;

$$\frac{1}{4\pi} \frac{e^{-|\kappa||\mathbf{r} + \mathbf{R} + \mathbf{T} - (\mathbf{r}' + \mathbf{R}' + \mathbf{T}')|}}{|\mathbf{r} + \mathbf{R} + \mathbf{T} - (\mathbf{r}' + \mathbf{R}' + \mathbf{T}')|} = \sum_L \sum_{L'} \bar{J}_L(E, \mathbf{r}) S_{\mathbf{R} + \mathbf{T}L, \mathbf{R}' + \mathbf{T}'L'} \bar{J}_{L'}(E, \mathbf{r}') \quad (57)$$

for  $(\mathbf{R}', \mathbf{T}') \neq (\mathbf{R}, \mathbf{T})$ .

The Bloch sum of  $S_{L, \mathbf{X}L'}$  gives the structure constant of  $\mathbf{k}$  as

$$S_{\mathbf{R}L, \mathbf{R}'L'}^{\mathbf{k}} = \sum_{\mathbf{T}} S_{\mathbf{R}L, \mathbf{R}' + \mathbf{T}'L'} \exp(i\mathbf{k}\mathbf{T}'), \quad (58)$$

Usually we use bare Coulomb at  $E = 0$ .

See the top of `strxq` defined in `strxq.F` (called in `hvcfp0.m.F`). This routine is for the one-center expansion of usual Bloch summed Hankels. (not for smooth Hankels). This result is finally converted to be the Bloch sum of the structure constant  $S_{\mathbf{R}L, \mathbf{R}'L'}^{\mathbf{k}}$  used in Eq. (59).

```
=====
NOTE in strxq.F; it says

-----
Cr Expansion Theorem: H_{RL}(r) = H_L(r-R)
Cr H_{RL}(E,r) = J_{R'L'}(E,r) * S_{R'L',RL}
Cr S_{R'L',RL} = 4 pi Sum_l C_{LL'L''} (-1)^l (-E)^(l+1'-1'')/2 H_L''(E,R-R')
-----
CAUTION!: We use R to denote MT position in the primitive cell;
thus this R is R+T in our notation.
-----
```

## 20.5 $\langle B|v|B \rangle$ part

Let us start from  $\langle B|v|B \rangle$  part. For this calculation, we need structure constant, and a few types of radial integrals. With the Bloch-summed structure constant  $\mathbf{strx} = 4\pi S_{\mathbf{R}L, \mathbf{R}'L'}^{\mathbf{k}}$ , we have

$$v^{\mathbf{k}}(\mathbf{r}, \mathbf{r}') = \sum_{\mathbf{T}} v(\mathbf{r} + \mathbf{T}, \mathbf{r}') e^{i\mathbf{k}\mathbf{T}} = e^2 \sum_{L, L'} \bar{J}_L(E, \mathbf{r} - \mathbf{R}) 4\pi S_{\mathbf{R}L, \mathbf{R}'L'}^{\mathbf{k}} \bar{J}_{L'}(E, \mathbf{r}' - \mathbf{R}'), \quad (59)$$

for  $\mathbf{R} \neq \mathbf{R}'$ . Note that we use  $e^2 = 1$  (a.u.) in `hvcfp0.m.F`. (See note at the beginning of `mkjp.F`. And note the normalization check at the end of `hvcfp0.m.F`;  $\langle \exp(i\mathbf{q}\mathbf{r}) | v | \exp(i\mathbf{q}\mathbf{r}) \rangle = 4\pi\Omega/|\mathbf{q}|^2$ , where  $\Omega$  is the cell volume.)

`strx` calculated by "call strxq@L806:hvccfp0.m.F" means  $4\pi S_{\mathbf{R}L, \mathbf{R}'L'}^k$ . This `strx` is used in call `vcoulq_4.nlx1` means  $(1+1)**2$  for  $R$  (`=ibas1`), `nlx2` as well.

Except the contribution for  $(\mathbf{R}, \mathbf{T}) = (\mathbf{R}', \mathbf{T}')$ , we can evaluate  $\langle B_{\mathbf{R}L\mu}^k(\mathbf{r}) | v^k(\mathbf{r}, \mathbf{r}') | B_{\mathbf{R}'L'\mu'}^k(\mathbf{r}') \rangle$ , from the

`rojb` integrals  $\rho^l(B_{\mathbf{R}L\mu})$  as

$$\rho^l(B_{\mathbf{R}L\mu}) = \int_0^R r \bar{J}_l(E, r) r B_{\mathbf{R}L\mu}(r) dr = \frac{1}{(2l+1)!!} \int_0^R \mathbf{rkpr}(\mathbf{r}) \mathbf{rprod}(\mathbf{r}) dr \quad (60)$$

Here  $B_{\mathbf{R}L\mu}(r)$  is the radial part of  $B_{\mathbf{R}L\mu}(\mathbf{r})$ . This `rojb` integrals are calculated in the subroutine `mkjb_4` in `mkjp.F`. We use radial functions  $\mathbf{rprod} = r B_{\mathbf{R}L\mu}(r)$ ,  $\mathbf{rkpr} = r \bar{J}_l(E, r)(2l+1)!!$ , and  $\mathbf{rkmr} = r \bar{H}_l(E, r)/(2l-1)!!$ . (Here  $\mathbf{rkpr}$  and  $\mathbf{rkmr}$  are propotional to  $r^l$  and  $r^{-l-1}$  for  $E = 0$ .)

The contribution from  $(\mathbf{R}, \mathbf{T}) = (\mathbf{R}', \mathbf{T}')$  should be added. This is  $\mathbf{k}$ -independent, and given by the

`sgbb` integral, which is also calculated in `mkjb_4`.

$$\begin{aligned} \sigma^l(B_{\mathbf{R}L\mu}, B_{\mathbf{R}L\nu}) &= 4\pi \int_0^R \int_0^R (r_<) \bar{J}_l(E, r_<) (r_>) \bar{H}_l(E, r_>) r B_{\mathbf{R}L\mu}(r) r' B_{\mathbf{R}L\nu}(r') dr dr' \\ &= \frac{4\pi}{2l+1} \int_0^R \int_0^R \mathbf{rkpr}(\mathbf{r}_<) \mathbf{rkmr}(\mathbf{r}_>) \mathbf{rprod}(\mathbf{n1}, \mathbf{r}) \mathbf{rprod}(\mathbf{n2}, \mathbf{r}') dr dr'. \end{aligned} \quad (61)$$

With the integrals `rojb` and `sgbb`, we can calculate  $\langle B | v | B \rangle$  in `vcoulq_4` as follows (`nbloch` means the total number of PB);

```
do ibl1= 1, nbloch
  ibas1= ibasbl(ibl1)
  n1   = nbl (ibl1)
  l1   = lbl (ibl1)
  m1   = mbl (ibl1)
  lm1  = lmb1(ibl1)
  do ibl2= 1, ibl1
    ibas2= ibasbl(ibl2)
    n2   = nbl (ibl2)
    l2   = lbl (ibl2)
    m2   = mbl (ibl2)
    lm2  = lmb1(ibl2)
    vcoul(ibl1, ibl2) =
&    rojb(n1, l1, ibas1) *strx(lm1, ibas1, lm2, ibas2)
&    *rojb(n2, l2, ibas2)
    if (ibas1==ibas2 .and. lm1==lm2) then
      vcoul(ibl1, ibl2) = vcoul(ibl1, ibl2) + sgbb(n1, n2, l1, ibas1)
      ! sigma-type contribution. onsite coulomb
    endif
  enddo
enddo
```

## 20.6 $RL$ expansion of $|P_{\mathbf{G}'}^k\rangle$

To evaluate  $\langle P_{\mathbf{G}}^k | v | P_{\mathbf{G}'}^k \rangle$ , we can use

$$\bar{P}_{\mathbf{G}}^k \equiv \left( 1 - \sum_{\mathbf{R}L}^{l \leq l_{\text{Pmax}}} P_{\mathbf{R}L} \right) e^{i(\mathbf{k}+\mathbf{G})\mathbf{r}}, \quad (62)$$

in the place of  $P_{\mathbf{G}}^k$  as long as we use large enough  $l_{\text{Pmax}}$ . Here  $P_{\mathbf{R}L}$  denotes the projection operator to extract the component of  $\mathbf{R}L$  contribution. In fact, we use large enough  $l_{\text{Pmax}}$ ;  $l_{\text{Pmax}} = 2 \times l_{\text{max}} = 2 * \text{LMXA}$ , where  $l_{\text{max}}$  denotes the maximum angular momentum for the expansion of eigenfunctions within MT (maximum  $l$  cutoff for  $\alpha_{\mathbf{R}u}^{\mathbf{k}n}$  in Eq. (4)). In the defalut setting, we use  $l_{\text{Pmax}} = 8$  since we use  $l_{\text{max}} = 4$ .

The matrix elements  $\langle P_1 | v | P_2 \rangle$  can be calculated as

$$\langle P_1(\text{phiphi}) | v | P_2(\text{phiphi}) \rangle = \sum_{\mathbf{G}_1' \mathbf{G}_1'' \mathbf{G}_2' \mathbf{G}_2''} \langle P_1(\text{phiphi}) | P_{1'} \rangle \langle P_{1'} | P_{1''} \rangle^{-1} \langle P_{1''} | v | P_{2''} \rangle \langle P_{2''} | P_{2'} \rangle^{-1} \langle P_{2'} | P_2(\text{phiphi}) \rangle, \quad (63)$$

where  $1 \equiv (\mathbf{k}, \mathbf{G}_1)$  and so on. Here  $P_1(\text{phiphi})$  indicates that an IPW made from a product of IPWs. The matrix elements  $\langle P_{2''} | P_{2'} \rangle^{-1}$  (stored into `PPOVLG, PPOVLI`) and  $\langle P_{2'} | P_2(\text{phiphi}) \rangle$  (stored into `PPOVLGG`) are given at `rdata4gw`.

## 20.7 Overlap matrix of PPOVL\* files

PPOVL\* files contains the overlap matrix of IPWs  $\langle P_G^k | P_{G'}^k \rangle$ . We have two types of  $\langle P_G^k | P_{G'}^k \rangle$ . One is for the Coulomb matrix (PPOVLG, PPOVLI). The other is for generating  $\langle G(\text{eigenfun.}) | G(\text{eigenfun.}) | G(\text{cou}) \rangle$ . (a product of IPWs of eigenfunctions can be expanded by IPWs for Coulomb matrix).

The overlap matrix elements  $\langle P_G^k | P_{G'}^k \rangle$  are generated in `rdata4gw`. These are read and allocated in the module `m_read_ppovl` (`rppovl.F`) when we call `getppx2`. We have "call `getppx2`" in the subroutine `melpn2t` in `ppbafp.fal.F`. The `melpn2t` is for generating the matrix element of  $\langle \text{IPW } \psi_i | \psi_j \rangle$ .

(1) PPOVLG + PPOVLI:

```
For q in qibze(1:3,1:nqnumt) (=IBZ + Q0P points),
number of IPWcou =ngc can be dependent of q.
We have <k+G|k+G'>= ppovl(ngc,ngc)
PPOVLG: G vectors as ngvecc(1:ngc).
PPOVLI: ppovl^-1(ngc,ngc). Inverse of PPOVLO
(PPOVLO is unused now. It is divided into PPOVLG and PPOVLI).
```

In principle the matrix element itself is k-independent,  
(just the difference of G vectors due to periodicity).  
But, for convenience, we generate them separately for each k.

(2) PPOVLGG:

```
This is used for <Gphi Gphi|Gc>.
ppovl(nggg,ngcgp) for nvggg,nvgcgp
Range of G for nvggg is |Gc+Gp+Gp|< |Gcou|+ |Gphi|+ |Gphi|
(triangle inequality.)
This is only for k=0 (Thus we remove k-dependence).
ngcgp
QpGcutggg = (2d0+1d-2)*QpGcut_psi+QpGcut_cou+ 2d0*pi/alat*dQpG
QpGcutgcp= (1d0+1d-2)*QpGcut_psi+QpGcut_cou+ 2d0* 2d0*pi/alat*dQQ
dQpG, dQQ is to enlarge range related to Q0P points.
```

## 20.8 $\langle P_G^k | v | P_{G'}^k \rangle$

To evaluate Eq. (63), we need to know its main part  $\langle P_G^k | v | P_{G'}^k \rangle$ . It is written as

$$\begin{aligned} \langle P_G^k | v | P_{G'}^k \rangle &\approx \langle \bar{P}_G^k | v | \bar{P}_{G'}^k \rangle = \langle \exp(i(\mathbf{k} + \mathbf{G})\mathbf{r}) | v | \exp(i(\mathbf{k} + \mathbf{G}')\mathbf{r}) \rangle - \sum_{\mathbf{RL}} \langle P_{\mathbf{RL}}^{\mathbf{k}+\mathbf{G}} | v | \exp(i(\mathbf{k} + \mathbf{G}')\mathbf{r}) \rangle \\ &\quad - \sum_{\mathbf{R}'L'} \langle \exp(i(\mathbf{k} + \mathbf{G}')\mathbf{r}) | v | P_{\mathbf{R}'L'}^{\mathbf{k}+\mathbf{G}'} \rangle + \sum_{\mathbf{RL}} \sum_{\mathbf{R}'L'} \langle P_{\mathbf{RL}}^{\mathbf{k}+\mathbf{G}} | v | P_{\mathbf{R}'L'}^{\mathbf{k}+\mathbf{G}'} \rangle, \end{aligned} \quad (64)$$

where  $P_{\mathbf{RL}}^{\mathbf{k}+\mathbf{G}}$  denotes the projection of PW to  $\mathbf{RL}$ , That is,  $P_{\mathbf{RL}}^{\mathbf{k}+\mathbf{G}} \equiv P_{\mathbf{RL}} e^{i(\mathbf{k}+\mathbf{G})\mathbf{r}}$ .

**The first term** The first term in the right-hand side of Eq. (64) is

$$\langle \exp(i(\mathbf{k} + \mathbf{G})\mathbf{r}) | v | \exp(i(\mathbf{k} + \mathbf{G}')\mathbf{r}) \rangle = \frac{4\pi\Omega}{|\mathbf{k} + \mathbf{G}|^2 + |E|} \delta_{\mathbf{G}\mathbf{G}'}, \quad (65)$$

because we simply use  $\exp(i(\mathbf{k} + \mathbf{G})\mathbf{r})$  (no prefactor for normalization) for IPW. Here  $E=eee$  is negative (or (almost) zero). This is coded by a line

```
if(ig1==ig2) vcoul(ip11,ip12) = fpivol/(absqg2(ig1) -eee)
@subr:vroulq_4@L281:mkjp.F.
```

**The second and third term** In the second term, we can replace  $v$  with  $\frac{4\pi\Omega}{|\mathbf{k}+\mathbf{G}'|^2+|E|}$  since  $v$  is diagonal for  $|\exp(i(\mathbf{k}+\mathbf{G}')\mathbf{r})\rangle$ , the third term as well. Without  $v$ , we have

$$\begin{aligned} \langle \exp(i(\mathbf{k}+\mathbf{G})\mathbf{r}) | P_{\mathbf{R}'L'}^{\mathbf{k}+\mathbf{G}'} \rangle &= \sum_{\mathbf{R}L} \langle P_{\mathbf{R}L}^{\mathbf{k}+\mathbf{G}} | P_{\mathbf{R}'L'}^{\mathbf{k}+\mathbf{G}'} \rangle \\ &= \sum_{\mathbf{R}L} (\text{pjyl}(\mathbf{k}+\mathbf{G}, L) \exp(i(\mathbf{k}+\mathbf{G})\mathbf{R}))^* \times R^{JJ}(|\mathbf{k}+\mathbf{G}|, |\mathbf{k}+\mathbf{G}'|, l) \\ &\quad \times \text{pjyl}(\mathbf{k}+\mathbf{G}', L) \exp(i(\mathbf{k}+\mathbf{G}')\mathbf{R}), \end{aligned} \quad (66)$$

where we use

$$\begin{aligned} P_{\mathbf{R}L}^{\mathbf{k}+\mathbf{G}}(\mathbf{r}) &= 4\pi i^l j_l(|\mathbf{k}+\mathbf{G}|r) Y_L(\widehat{\mathbf{k}+\mathbf{G}}) Y_L(\widehat{\mathbf{r}}) \exp(i(\mathbf{k}+\mathbf{G})\mathbf{R}) \\ &= \text{pjyl}(\mathbf{k}+\mathbf{G}, L) \bar{J}_l(|\mathbf{k}+\mathbf{G}|r) Y_L(\widehat{\mathbf{r}}) \exp(i(\mathbf{k}+\mathbf{G})\mathbf{R}), \end{aligned} \quad (67)$$

where  $\mathbf{r}$  is measured from the center  $\mathbf{R}$ . Here we use  $\text{pjyl}_-$  defined as

$$\text{pjyl}_-(\mathbf{k}+\mathbf{G}, L) = 4\pi i^l |\mathbf{k}+\mathbf{G}|^l Y_L(\widehat{\mathbf{k}+\mathbf{G}}) \quad (68)$$

(recall the definition of  $\bar{J}_l$ . In codes, `cy(lm)*yl(lm) = Y_L(\widehat{\mathbf{k}+\mathbf{G}})`.) Search `pjyl_-` in `mkjp.F`. The Bessel functions appear here in the expansion of PW; see Eq. (53).  $R^{JJ}(|\mathbf{k}+\mathbf{G}|, |\mathbf{k}+\mathbf{G}'|, l)$  is given as

$$R^{JJ}(|\mathbf{k}+\mathbf{G}|, |\mathbf{k}+\mathbf{G}'|, l) = \int_0^R r^2 \bar{J}_l(|\mathbf{k}+\mathbf{G}|r) \bar{J}_l(|\mathbf{k}+\mathbf{G}'|r) dr, \quad (69)$$

which can be calculated by the wronskian (`wronskj`) by the formula

$$R^{JJ}(\kappa_A, \kappa_B, l) = \int_0^R r^2 \bar{J}_l(\kappa_A r) \bar{J}_l(\kappa_B r) dr = R^2 \frac{\bar{J}_l(\kappa_A R) \frac{d\bar{J}_l(\kappa_B R)}{dR} - \frac{d\bar{J}_l(\kappa_A R)}{dR} \bar{J}_l(\kappa_B R)}{\kappa_A^2 - \kappa_B^2} \Big|_{r=R} = -\text{fjj} \quad (70)$$

(`-fjj` is used in `mkjp.F`. In codes, the contributions to the second and third terms of Eq. (64) due to  $\mathbf{R}L$  components are given as (simplified for illustration)

```
fouvp_ig1_ig2 = fpi/(absqg2(ig1)-eee)      &
               * dconjg(pjyl_(lm2,ig1)*phase(ig1,ibas2))  &
               * (-fjj(1)) * pjyl_(lm2,ig2)*phase(ig2,ibas2)
fouvp_ig2_ig1 = fpi/(absqg2(ig2)-eee)      &
               * dconjg(pjyl_(lm2,ig2)*phase(ig2,ibas2))  &
               * (-fjj(1)) * pjyl_(lm2,ig1)*phase(ig1,ibas2)
```

Look for the keyword `fourvp` in `mkjp.F`. Correspondences are

```
fpi --> 4 pi
absqg2(ig1) --> |q+G1|**2
-eee --> |E|
lm2 --> L
ibas2 --> R
```

**The forth term** The last term of Eq. (64) can be calculated essentially the same manner with  $\langle B|v|B \rangle$ , where we use the Bessel function instead of  $B_{\mathbf{R}L\mu}(r)$  appeared in Sec.20.5. Then we define integrals `rojpb` and `sgpp` defined as (in `fpgw/gwsr/mkjp.F`);

$$\text{rojpb}(\mathbf{R}L) = \text{pjyl}_- \exp(i(\mathbf{q}+\mathbf{G})\mathbf{R}) \rho^l(\bar{J}_l) \quad (71)$$

$$\begin{aligned} \text{sgpp}(\mathbf{R}L, \mathbf{G}, \mathbf{G}') &= \text{pjyl}_-(\text{ig1}) \exp(-i(\mathbf{q}+\mathbf{G})\mathbf{R}) \text{pjyl}_-(\text{ig2}) \exp(i(\mathbf{q}+\mathbf{G}')\mathbf{R}) \\ &\quad \times \text{radsig}, \\ &\quad \text{where } \text{radsig} = \sigma^l(\bar{J}_l(|\mathbf{q}+\mathbf{G}|r), \bar{J}_l(|\mathbf{q}+\mathbf{G}'|r)). \end{aligned} \quad (72)$$

Thus, `rojpb` and `sgpp` made of coefficients for expansion and radial integral. Search `sgpp_ig1_ig2` in `mkjp.F`.

## 20.9 $\langle P|B \rangle$ part

$$\begin{aligned} \langle P_{\mathbf{G}}^{\mathbf{k}} | v | B_{\mathbf{R}L\mu}^{\mathbf{k}}(\mathbf{r}) \rangle &= \langle \exp(i(\mathbf{k}+\mathbf{G})\mathbf{r}) | v | B_{\mathbf{R}L\mu}^{\mathbf{k}}(\mathbf{r}) \rangle - \sum_{\mathbf{R}'L'} \langle P_{\mathbf{R}'L'}^{\mathbf{k}+\mathbf{G}} | v | B_{\mathbf{R}L\mu}^{\mathbf{k}}(\mathbf{r}) \rangle \\ &= \text{fouv}(\mathbf{G}, \mathbf{R}L\mu) - \sum_{\mathbf{R}'L'} \text{rojpb} * \text{strx} * \text{rojpb} \end{aligned} \quad (73)$$

The first term is stored in `fouv`(`ngc, nxx, nlxx, nbas`) allocated at `L824:hvccfp0.m.F`. Search `fouv` in `mkjp.F`. Since  $v$  is diagonal to PWs, we can evaluate this in the similar manner of Eq. (66). The second term can be evaluated from `roj` and `sgp` in the same manner of last section.

...xxxxx under construction xxxxx...  
(we will detail a little more...)

## 21 Improved offset- $\Gamma$ method; $W(\mathbf{k}=0)$ averaged in the $\Gamma$ cell.

The offset- $\Gamma$  method, originally invented for Ref.[18] by Kotani (it is described in Ref.[13]), was a key to perform accurate  $GW$  calculation in our papers. It is for the integration of  $\mathbf{k}$  in Eqs.(22) and (27), where we have the integrands that diverge at  $\mathbf{k} \rightarrow 0$ . The original offset  $\Gamma$  method works well for highly symmetric systems; however, it may be problematic to apply to less symmetric systems, because the anisotropic divergence of the integrands may not be treated accurately.

Here we show an improved offset- $\Gamma$  method, which treats the anisotropy of  $W(\mathbf{k}, \omega)$  accurately. In the followings, we use expression  $W(\mathbf{k})$  for simplicity (omit subscripts and  $\omega$ ) instead of  $W_{\mu\nu}(\mathbf{k}, \omega)$ , since we are concerned with the  $\mathbf{k}$  integral here.

Let us give a formula for calculating  $\int_{\text{BZ}} f(\mathbf{k}) d^3k$  using a discrete sum on  $\mathbf{k}$ -mesh, where  $f(\mathbf{k}) = G(\mathbf{q} - \mathbf{k}) \times W(\mathbf{k})$ . For the  $\mathbf{k}$ -mesh, we use

$$\mathbf{k}(i_1, i_2, i_3) = 2\pi \left( \frac{i_1}{N_1} \mathbf{b}_1 + \frac{i_2}{N_2} \mathbf{b}_2 + \frac{i_3}{N_3} \mathbf{b}_3 \right),$$

where  $\mathbf{b}_1, \mathbf{b}_2$ , and  $\mathbf{b}_3$  are the primitive reciprocal vectors (the same as the Eq.(47) in Ref.[13]). The 1st BZ is divided into  $N = N_1 \times N_2 \times N_3$  microcells ( $i_1 = 0, 1, \dots, N_1 - 1$ , and also the same for  $i_2$  and  $i_3$ ). The microcell including the  $\Gamma$  point is called the  $\Gamma$  cell [22]. The main problem is how to evaluate the contribution of the  $\Gamma$  cell. The divergent part of  $f(\mathbf{k})$  behaves  $\approx$  (analytic function of  $\mathbf{k}$ ) /  $(\mathbf{k}^T \mathbf{L} \mathbf{k})$ , where  $\mathbf{k}^T$  denotes the transpose of  $\mathbf{k}$ ;  $\mathbf{L}$  is a  $3 \times 3$  Hermitian matrix [14]. We neglect an odd part of  $\mathbf{k}$  in the above (analytic function of  $\mathbf{k}$ ) because it has no contribution to the integral around  $\mathbf{k} = 0$ . Thus it is sufficient to consider the integral for  $f(\mathbf{k})$  whose divergent parts behave as  $f(\mathbf{k}) = \sum_L \frac{f_L Y_L(\mathbf{k})}{|\mathbf{k}|^2}$  at  $\mathbf{k} \rightarrow 0$ , where  $l$  of  $L \equiv (l, m)$  is restricted to be even numbers. We evaluate the integral using the formula

$$\int_{\text{BZ}} f(\mathbf{k}) d^3k \approx \frac{1}{N} \sum_{\mathbf{k} \neq 0} f(\mathbf{k}) + \sum_L f_L w_L + \frac{1}{N} \tilde{f}, \quad (74)$$

which is introduced in Ref.[22]. Here the weight  $w_L$  is determined in a manner as follows, so as to take into account the contributions of the divergent part of  $f(\mathbf{k})$  at  $\mathbf{k} \rightarrow 0$  in the  $\Gamma$  cell.  $\tilde{f}$  is the constant part of  $f(\mathbf{k})$  at  $\mathbf{k} \rightarrow 0$ .

To determine  $w_L$ , we can use the following procedure instead of that given in Ref.[22]. We first introduce the auxiliary function

$$F_L(\mathbf{k}) = \sum_{\mathbf{G}} \frac{\exp(-\alpha |\mathbf{k} - \mathbf{G}|^2) Y_L(\widehat{\mathbf{k} - \mathbf{G}})}{|\mathbf{k} - \mathbf{G}|^2}. \quad (75)$$

This is a generalization of an auxiliary function used in the offset- $\Gamma$  method (then we only used  $F_{00}$  [13]). We usually take the  $\alpha \rightarrow 0$  limit, or a sufficiently small  $\alpha$  instead. Let us apply Eq. (74) to  $F_L(\mathbf{k})$ . Then we can evaluate the left-hand side of Eq. (74) exactly (the exact values are zero except for  $L = (0, 0)$ ). On the other hand, the first and third terms on the right-hand side of Eq. (74) can be evaluated numerically. In addition, we know that  $f_{L'}$  for  $F_L(\mathbf{k})$  is unity for  $L' = L$ , and zero otherwise. Thus we can determine  $w_L$  in Eq. (74) so that Eq. (74) is exactly satisfied for  $F_L(\mathbf{k})$  for any  $L$ .

Let us apply Eq. (74) to  $f(\mathbf{k}) = G(\mathbf{q} - \mathbf{k}) \times W(\mathbf{k})$ . Then we perform an approximation taking only the most divergent term in  $W(\mathbf{k})$  in addition to its analytic part. That is, we use

$$W_{\mu\nu}(\mathbf{k}) \sim \widetilde{W}_{\mu\nu}(\mathbf{0}) + \frac{4\pi}{\mathbf{k}^T \mathbf{L} \mathbf{k}} \delta_{1\mu} \delta_{1\nu} \quad (76)$$

at  $\mathbf{k} \rightarrow 0$ .  $\widetilde{W}_{\mu\nu}(\mathbf{0}) = 0$  for  $\mu = 1$  or  $\nu = 1$ . See Eq.(36) in Ref.[14] to know what is neglected

in the approximation of Eq. (76).

Then we finally obtain

$$\int_{\text{BZ}} d^3k G(\mathbf{q} - \mathbf{k}) W(\mathbf{k}) \approx \overline{\sum G(\mathbf{q} - \mathbf{k}) W(\mathbf{k})}, \quad (77)$$

where its right-hand side is defined as

$$\begin{aligned} & \overline{\sum G(\mathbf{q} - \mathbf{k}) W(\mathbf{k})} \\ & \equiv \frac{1}{N} \sum_{\mathbf{k} \neq 0} G(\mathbf{q} - \mathbf{k}) W(\mathbf{k}) + \frac{1}{N} G(\mathbf{q}) \overline{W}(\mathbf{0}), \end{aligned} \quad (78)$$

$$\overline{W}(\mathbf{0}) \equiv N \sum w_L W_L + \widetilde{W}(\mathbf{0}). \quad (79)$$

Here  $\overline{W}(\mathbf{0})$  is an average of  $W$  in the  $\Gamma$  cell. With this  $\overline{W}(\mathbf{0})$ , we can evaluate integrals just as the sum on the discrete  $\mathbf{k}$ -mesh. When the matrix  $\mathbf{L}$  is given (a method of calculating  $\mathbf{L}$  is given in the next paragraph), the non-analytic (but non-divergent) function  $\mathbf{k}^T \mathbf{L} \mathbf{k} / |\mathbf{k}^2|$  is expanded in the spherical harmonics. Then  $W_L$  is calculated for a given  $\mathbf{L}$  in the manner shown in Ref.[14]. We can evaluate the accuracy of integrals with a discrete  $\mathbf{k}$ -mesh in combination with the approximation of Eq. (76) by calculations while changing the size of the  $\mathbf{k}$ -mesh.

The remaining problem is how to calculate the matrix  $\mathbf{L}$  in Eq. (76); there are two possible ways. One is the  $\mathbf{k} \cdot \mathbf{p}$  method (perturbation) used in Ref.[14]; the other is the numerical method to calculate  $\mathbf{L}$  at some  $\mathbf{k}$  points near  $\mathbf{k} = 0$ . Here we use the latter method. Because of the point-group symmetry of the system,  $\mathbf{L}$  can be expressed by the linear combination of invariant tensors  $\mu_{ij}^g$  for the symmetry of the unit cell,

$$L_{ij}(\omega) = \sum_{g=1}^{N_g} a_g(\omega) \mu_{ij}^g, \quad (80)$$

where  $g$  is the index of the invariant tensor. The number of  $g$ 's  $N_g$ , can be from one (cubic symmetry) through six (no symmetry). It is possible to determine the coefficient  $a_g(\omega)$  from the dielectric functions  $\hat{\mathbf{k}}_{0i}^T \mathbf{L} \hat{\mathbf{k}}_{0i}$  calculated at  $\{\mathbf{k}_{0i}\}$  points around  $\mathbf{k} = 0$ , where  $\{\mathbf{k}_{0i}; i = 1, N_g\}$  is a set of the offset- $\Gamma$  points. The offset- $\Gamma$  points are chosen so that the conversion matrix from  $\hat{\mathbf{k}}_{0i}^T \mathbf{L}(\omega) \hat{\mathbf{k}}_{0i}$  to  $a_g(\omega)$  is not numerically degenerated. The length  $|\mathbf{k}^{0i}|$  can be chosen to be sufficiently enough, but avoiding numerical error as the average of  $W(\mathbf{k})$  in the  $\Gamma$  cell. The improved offset- $\Gamma$  method shown here can be applicable even to metal cases, as long as  $\hat{\mathbf{k}}_{0i}^T \mathbf{L}(\omega) \hat{\mathbf{k}}_{0i}$  contains the contribution of intraband transition.

## 22 hx0fp0.sc.m.F. $W(\mathbf{k}, \omega)$ calculation

. .... under construction ....

## 23 self-energy

. .... under construction ....

## 24 Fourier transformation of non-local quantity

We have "call bloch" in `lm7K/fp/bndfp.F`. This is for the three dimensional FFT. The usual FT is by

$$f(\mathbf{T}) = \sum_{\mathbf{k}} f(\mathbf{k}) \exp(i\mathbf{k}\mathbf{T}), \quad (81)$$

where  $\{\mathbf{k}\}$  is are on the regular mesh points. The total number of its members is  $N_1 \times N_2 \times N_3$ . (the number is the same as that of  $\{\mathbf{T}\}$ ). Note that we have periodicity both in  $\mathbf{k}$  points and in  $\mathbf{T}$  points. Because of the periodicity, the range of  $\{\mathbf{k}\}$  is not unique, the range of  $\{\mathbf{T}\}$  as well.

Let us think about non-local quantity which is dependent on  $\mathbf{T} - \mathbf{T}'$ . Then we have

$$f(\mathbf{R}\mathbf{T}, \mathbf{R}'\mathbf{T}') = \sum_{\mathbf{k}} f_{\mathbf{R}\mathbf{R}'}(\mathbf{k}) \exp(i\mathbf{k}(\mathbf{T} - \mathbf{T}')), \quad (82)$$

In practical calculations (static version of self-energy treated by `bloch` called in `fp/bndfp.F`), we first calculate  $f_{\mathbf{R}\mathbf{R}'}(\mathbf{k})$  on  $\mathbf{k}$  of regular mesh points. Then we need to obtain its real-space representation  $f(\mathbf{R}\mathbf{T}, \mathbf{R}'\mathbf{T}')$ . Because of the periodicity, we have ambiguity for the choice of possible  $|\mathbf{T} - \mathbf{T}'|$ . If we introduce  $\bar{\mathbf{T}} = \mathbf{T} - \mathbf{T}'$ , Eq. (82) is written as  $f(\mathbf{R}\bar{\mathbf{T}}, \mathbf{R}'0) = \sum_{\mathbf{k}} f_{\mathbf{R}\mathbf{R}'}(\mathbf{k}) \exp(i\mathbf{k}\bar{\mathbf{T}})$  because of translational symmetry.

A reasonable choice is that we allow  $\bar{\mathbf{T}}$  which satisfy  $|\mathbf{R} - \mathbf{R}' + \bar{\mathbf{T}}| \leq \eta_{\text{FTmax}}$ . Here we should choose  $\eta_{\text{FTmax}}$  so that the number of allowed  $\{\bar{\mathbf{T}}\}$  is  $N_1 \times N_2 \times N_3$ . However, it can be not possible, because of denegeracy; for the largest value of  $|\mathbf{R} - \mathbf{R}' + \bar{\mathbf{T}}|$  in the allowed  $\{\bar{\mathbf{T}}\}$ , we may have some of  $\bar{\mathbf{T}}$  (we say degenerated). Then we need to give fractional weight for such  $\bar{\mathbf{T}}$ .

To get a list of  $\bar{\mathbf{T}}$ , we need to collect them satisfying  $|\mathbf{R} - \mathbf{R}' + \bar{\mathbf{T}}| < \eta_{\text{FTmax}}$ .  $\eta_{\text{FTmax}}$  should be automatically chosen. However, in the "bloch" subroutine, this is too primitive yet(aug2015); we need to specify possible upper limit of "range of allowed pairs" ( $\mathbf{R}\bar{\mathbf{T}}, \mathbf{R}'0$ ) by hand. (RSRNGE in `ctrl` file). This should be fixed in future. In the current version `iaxs (=sham%iv_a_oiaxs)` contains such pair table. It is generated by call `hft2rs` in call `seneinterp` in `bndfp.F`, I think. We will have to replace "bloch" with better version. Pair table must be generated in a simple manner( with the technique of `getgv2` (`getgv2` is given in `fpgw/gwsrsrc/getgv2.F` and `lm7K/subs/pairs.F`).

## 25 Interpolation of the self-energy in the Brillouin zone

Here we show an interpolation procedure for giving  $V_{\mathbf{k}}^{\text{xc}}$  at any  $\mathbf{k}$ , from  $V_{\mathbf{k}}^{\text{xc}}$  calculated only at the regular mesh points  $\mathbf{k}(i_1, i_2, i_3)$ . This interpolation is used for the offset- $\Gamma$  method that requires  $W(\omega)$  at  $\{\mathbf{k}_{0i}\}$ ; to calculate this  $W(\omega)$ , we need eigenfunctions and eigenvalues not only at the regular mesh points  $\mathbf{k}(i_1, i_2, i_3)$  but also at  $\mathbf{k}(i_1, i_2, i_3) + \mathbf{k}_{0i}$ . This interpolation is also useful for plotting energy bands. A key point of the interpolation is that  $V^{\text{xc}}$  is expanded in real space in highly localized MTOs as follows.

At the end of step (IV) in Sec.??, we obtain the matrix elements  $\langle \Psi_{\mathbf{k}n} | \Delta V_{\mathbf{k}}^{\text{xc}} | \Psi_{\mathbf{k}m} \rangle$  on the regular mesh points of  $\mathbf{k}$ , where  $\Delta V_{\mathbf{k}}^{\text{xc}} = V_{\mathbf{k}}^{\text{xc}} - V_{\mathbf{k}}^{\text{xc,LDA}}$ . Then it is converted to the representation in the APW and MTO bases as

$$\langle \chi_a^{\mathbf{k}} | \Delta V_{\mathbf{k}}^{\text{xc}} | \chi_b^{\mathbf{k}} \rangle = \sum_{n,m} (z^{-1})_{an}^* \langle \Psi_{\mathbf{k}n} | \Delta V_{\mathbf{k}}^{\text{xc}} | \Psi_{\mathbf{k}m} \rangle z_{bm}^{-1}, \quad (83)$$

where we use the simplified basis index  $a$ , which is the index for specifying a basis ( $\mathbf{R}Lj$  for MTO or  $\mathbf{G}$  for APW). Thus  $\chi_a^{\mathbf{k}}$  denotes the APWs or MTOs in Eq. (4);  $z_{na}(\mathbf{k})$  (is omitted for simplicity) denotes the coefficients of the eigenfunctions at  $\mathbf{k}$ , that is,  $z_{\mathbf{R}Lj}^n$  and  $z_{\mathbf{G}}^n$  in Eq. (4) together. This  $z_{an}$  is identified as a conversion matrix that connects eigenfunctions (band index  $n$ ) and the APW and MTO bases (basis index  $a$ ).

To obtain real-space representation of  $\Delta V^{\text{xc}}$ , we need a representation expanded in the basis that consist of the Bloch-summed localized orbitals, which are periodic for  $\mathbf{k}$  in the BZ. However, this is not the case for the APWs in Eq. (83). To overcome this problem, we use an approximation in which we only take the matrix elements related to MTOs, that is, the elements  $\langle \chi_a^{\mathbf{k}} | \Delta V_{\mathbf{k}}^{\text{xc}} | \chi_b^{\mathbf{k}} \rangle$  where  $a$  and  $b$  specify MTOs. This means that the part of  $\Delta V^{\text{xc}}$  related to APWs is projected onto the basis of MTOs. This approximation can be reasonable as long as the main part of  $\Delta V^{\text{xc}}$  can be well expanded in MTOs, although we need numerical tests to confirm the accuracy as shown in Sec.?. Then we obtain a real-space representation of  $\Delta V^{\text{xc}}$  expanded in MTOs from the MTO part of  $\langle \chi_a^{\mathbf{k}} | \Delta V_{\mathbf{k}}^{\text{xc}} | \chi_b^{\mathbf{k}} \rangle$  by Fourier transformation. Then we can have interpolated  $\Delta V^{\text{xc}}$  at any  $\mathbf{k}$  by inverse Fourier transformation. Since we use highly localized MTOs, this interpolation is more stable than the previous one in FP-LMTO-QSGW [13]. The complicated interpolation procedure given in Sec.II-G in Ref.[13] is

no longer necessary.

To reduce the computational time, we calculate the matrix elements  $\langle \Psi_{\mathbf{k}n} | \Delta V_{\mathbf{k}}^{\text{xc}} | \Psi_{\mathbf{k}m} \rangle$  only up to the states whose eigenvalues are less than  $E_{\text{MAX}}^{\Sigma}$ . Then the high energy parts of the matrix elements are assumed to be diagonal, where their values are given by a simple average of calculated diagonal elements.

## 25.1 General cautions for developers

**gwsc** is the main script to perform QSGW. Sec.6 gives an overview. Sec.11 explain main output files. Sec. 13 explains all i/o files.

At first, note that one-body part **lmv7** and **fpgw** are divided, mainly because of historical reasons. Make procedure is complicated, but automatic by **ecalj/InstallAll.\*** (See. **ecalj/README.md**).

Main make system of **ecalj** is in **ecalj/InstallAll.\***. As you see in it, makefile for **fpgw** (GW part) is located at **fpgw/gwsrc/exec/makefile**. (memo: apr2015. A little too much complicated because of duplicated definition of subroutines... We need to simplify variables...).

Cautions are;

- Integrated Make system; **ecalj/InstallAll.\***  
For development, see **ecalj/InstallAll.ifort** (.gfortran) This let you know how to invoke make. The **ecalj** consists of three make procedure. **lmv7**, **fpgw/exec/**, **fpgw/Wannier**.
- Install test  
At the end of **InstallAll.\***, we have **make mpi\_size=4 all** at **ecalj/TestInstall**. This is an unique way to run a series of installation tests.
- Machine dependence  
For **fpgw/exec/**, Machine-dependent part is given by a file such as **make.inc.gfortran**, which is included in the makefile by the variable **PLATFORM**. For **lmv7**, we have **lmv7/MAKEINC/**, where we have files which describes machine-dependences.
- Module dependency  
**moduledepends.inc** is automatically generated by **checkmodule** (python code; I sometimes need to do make init).
- CPU time and Memory measurements  
At the bottom of makefile, we have a mechanism to insert clock routines in source code. For example, **hsfp0.sc.m.F** is converted to **time\_hsf0.sc.m.F**, and then compiled. Time measurement is specified directive lines **!TIME0\\_number-->!TIME1\\_number**. For example, see **sxcf\_fa12.sc.F**. The directive lines **!TIME0\\_number --->!TIME1\\_number** specify intervals to measure time as shown at the bottom of console output file **lx0** (see **gwsc** script).

See **fpgw/exec/makefile** to understand how to make binaries for **gw** part. We can make binaries by **make PLATFORM=ifort LIBMATH=-mkl** at the directory.

Other cautions for computer codes;

- We often use modules. A typical example is **use m\_genallcf\_v3,only: ...**. For example, see **hsfp0.sc.m.F**, which is for the calculation of  $W - v$ . For **call genallcf\_v3** in it, all data for the **use m\_genallcf\_v3,only:** are allocated. Thus we can use these data after **call genallcf\_v3** in the code **hsfp0.sc.m.F**.
- Methods(functions) in modules are keys to learn **fpgw/** codes. For example, we have **geteval**(eigenvalues), **readcphi**(coefficient of eigenfunction for MTO part), **readgeig**(coefficient of APW part), **get\_zmel** (**<phi|phi MPB>**). In cases, we have initialization routines such as **readqgcou()** defined in **readeigen.F**. After it is called, we can access to all data in module **m\_readqgcou**. In principle, this kind of initialization routines must be called at the top of main programs... But not organized yet. In addition, it may be better to allocate even scalar in **fortran2003**. But such new features in **fortran2003** is still buggy (at least in **ifort15**) as long as I tested.

- A possible mechanism to make things safer is given by a variable `done_genallcf_v3` defined in `genallcf_mod.F`. Observe how it works in this routine. This ensures that `genallcf_v3` is called only once in a program. Thus variables in `m_genallcf_v3` have uniqueness (But we have no simple way to make write protections for them. You know a way?) In my opinion, Fortran is not suitable to write long computer codes. It is better to use glue languages such as Python or Bash, as I did in `gwsc`...
- `nbas` is the number of MT sites in the primitive cell. We use `ibas` for a loop of `do ibas=1,nbas`. This is a general rule; another example is `iqbz=1,nqibz` where `nqibz` is the number of irreducible q points.
- `getkeyvalue` defined in `fpgw/gwsrc/keyvalue.F` is an universal i/o routine for GWinput. Its arguments can be one of types among "logical, int, real, int array, real array". Do `grep 'call getkeyvalue' for fpgw/*/*.F` to find out how to use it.

## 26 Overview of gwsc and other scripts

The `fpgw/exec/gwsc` is the main script to run QSGW. After we finish one-body self-consistent calculation, we run `echo 0|lmfgw`, resulting small files. See Sec.6. Then we run `qg4gw` to generate q+G vectors stored in `QGpsi, QGcou, Q0P` files, in addition to `EPSwklm`, which is for offset-Gamma method ???. Then we run `lmfgw-MPI` which is to calculate eigenfunctions and eigenvalues (and some quantities) required for successive main part of QSGW calculation. We recommend you to examine this first.

For the one-shot GW, we have another script `gw_lmfn`. For dielectric functions (and for  $\chi_{+-}^0$ , we have `eps*`. These are slightly different from `gwsc`, calling slightly different version of Fortran programs. Wannier function calculations can be done by `genMLWF`, which not only generates Wannier functions (tight-binding parameters), but also W and U between Wannier functions (RPA and cRPA) together. It is in `fpgw/Wannier` directory.

xx

In Sec. 21, we show a new improvement in the offset- $\Gamma$  method, which is made in order to treat the  $\mathbf{k} \rightarrow 0$  divergence of the integrand for the self-energy calculation. This improvement can correctly capture the anisotropy of the screened Coulomb interaction, although the previous offset- $\Gamma$  method in FP-LMTO-QSGW [13] can be problematic for treating anisotropic systems.

In Sec. 25, we explain the interpolation procedure of  $V_{\mathbf{k}}^{\text{xc}}(\mathbf{r}, \mathbf{r}')$ . The procedure is simplified in comparison with that used in FP-LMTO-QSGW.

## A Block inversion used for dielectric functions and downfolding

See Christoph's and Pick's paper

$$\begin{pmatrix} P & Q \\ R & S \end{pmatrix} \begin{pmatrix} W & -WQS^{-1} \\ -S^{-1}RW & S^{-1} + S^{-1}RWQS^{-1} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad (84)$$

where  $P$  and  $S$  are square matrices, and

$$W = (P - QS^{-1}R)^{-1}. \quad (85)$$

We refer  $X = -WQS^{-1}$  and  $Y = -S^{-1}RW$ .

Proof:

$$(1, 1) \text{ component} = PW - QS^{-1}RW = (P - QS^{-1}R)W = 1, \quad (86)$$

$$\begin{aligned} (1, 2) \text{ component} &= -PWQS^{-1} + QS^{-1} + QS^{-1}RWQS^{-1} \\ &= (-PW + 1 + QS^{-1}RW)QS^{-1} = (-(P - QS^{-1}R)W + 1)QS^{-1} = 0 \end{aligned} \quad (87)$$

$$(2, 1) \text{ component} = RW - SS^{-1}RW = 0, \quad (88)$$

$$(2, 2) \text{ component} = -RWQS^{-1} + SS^{-1} + SS^{-1}RWQS^{-1} = 1 \quad (89)$$

## B Downfolding

Downfolding is a general concept which often appears in physics in different context. It is based on the Block inversion Eq.84. This appears for the inversion of one-body problem, or divide the Fock space for many-body theory. (divide the Fock space into two Hilbert spaces; one-particle excited states and states with more than one-particles).

For exaple, the Green function is the inversion of the matrix  $\omega - H$ , where  $H$  is divided into to

$$\begin{pmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{pmatrix}. \quad (90)$$

If we have  $H_{12} = H_{21} = 0$ , we have  $G_{11}^0 = 1/(\omega - H_{11})$  as the main part of Green function. This is completely separated from from the residual part  $G_{22}^0 = 1/(\omega - H_{22})$ .

When  $H_{12}$  and  $H_{21}$  are non-zero, we have to take into their effect by perturbation, or by the block inversion Eq.84. Then we have

$$\begin{pmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{pmatrix} = \begin{pmatrix} G_{11} & -G_{11}H_{12}G_{22}^0 \\ -G_{22}^0H_{21}G_{11} & G_{22}^0 + G_{22}^0H_{21}G_{11}H_{12}G_{22}^0 \end{pmatrix}, \quad (91)$$

where  $W$  in Eq. (84) is  $G_{11}$ . Note that the  $\omega$  dependence is in  $G_{11}^0$  and  $G_{22}^0$ . Here  $G_{11}$  given as (See Eq. (85)).

$$G_{11} = \frac{1}{\omega - H_{11} - H_{12}G_{22}^0H_{21}}. \quad (92)$$

Then  $H_{12}G_{22}^0H_{21}$  is identified as the self-energy.

There are possible cases about how to choose Hilbert space  $\Omega_1$  and  $\Omega_2$  corresponding to the division Eq. (90).

- In the one-body problem, for example, we take  $\Omega_1$  as low energy part and  $\Omega_2$  as high energy part. or 3d parts and others.
- In a case of many-body theory,  $\Omega_1$  is the one-particle Fock space. Then  $G_{11}$  is the one-body propagator, and  $G_{22}$  is many-body (two- and more particles-) propagator.
- We may take  $\Omega_1$  as the model space,  $\Omega_2$  as the residual space. Then we make like to identify  $H_{11}$  as the Hubbard Hamiltonian. However, it is not so simple since  $H_{11}$  contains

screening effect due to the degree of freedom of  $\Omega_2$ . We have to consider a little more complicated downfolding procedure.

Warn: not be confused with the division of many-body Hamiltonian  $H$  into  $H_0 + (H - H_0)$  for perturbation.

## C Causality and analytic property

Causality means "cause gives result". This is represented by the step function, for example, as  $\theta(t - t') \exp(i\omega_0(t - t'))$ , whose FT gives  $1/(\omega - \omega_0 - i\delta)$ . Thus the position of pole (upper or lower plane) is important to determine the direction of time (real time representation).

Sum rule is related but a little different. For example, sum rule for Imaginary part of  $G_{11}$  is controlled only by the behavior  $G_{11}(\omega)$  at  $|\omega| \rightarrow \infty$ . Thus, as long as  $H_{12}G_{22}^0H_{21} \propto 0$  for  $|\omega| \rightarrow \infty$ , the sum rule is satisfied.

## D Spherical Harmonics and Real harmonics in ecalj

In our GW code, we user real harmonics  $y_{lm}(\hat{\mathbf{r}})$ , instead of the usual sperical (complex) harmonics  $Y_{lm}(\hat{\mathbf{r}})$  in the real implimentation. The coefficients of eigenfunctions and so on are ordered as, e.g. ( $m = -2, m = -1, m = 0, m = 1, m = 2$ ) for  $l = 2$ . For example, **LMXA=4**, we have **(4+1)\*\*2=25** harmonics, ordered as  $y_{00}, y_{-11}, y_{01}, y_{11}, y_{-22}, y_{-12}, \dots, y_{22}, y_{-33}, \dots, y_{33}, y_{-44}, \dots, y_{44}$ .

$y_{lm}(\hat{\mathbf{r}})$  is defined from  $Y_{lm}(\hat{\mathbf{r}})$ . (Note  $\hat{\mathbf{r}} = (\theta, \phi)$ ). The definition of the real harmonics is the same as what is used in lmf.

$$y_{l0}(\hat{\mathbf{r}}) \equiv Y_{l0}(\hat{\mathbf{r}}). \quad (93)$$

$$y_{lm}(\hat{\mathbf{r}}) \equiv \frac{1}{\sqrt{2}} [(-1)^m Y_{lm}(\hat{\mathbf{r}}) + Y_{l-m}(\hat{\mathbf{r}})]. \quad (94)$$

$$y_{l-m}(\hat{\mathbf{r}}) \equiv \frac{1}{\sqrt{2}i} [(-1)^m Y_{lm}(\hat{\mathbf{r}}) - Y_{l-m}(\hat{\mathbf{r}})]. \quad (95)$$

, where  $m > 0$ . Or Equivalently,

$$Y_{l0}(\hat{\mathbf{r}}) \equiv y_{l0}(\hat{\mathbf{r}}). \quad (96)$$

$$Y_{lm}(\hat{\mathbf{r}}) \equiv \frac{(-1)^m}{\sqrt{2}} [y_{lm}(\hat{\mathbf{r}}) + iy_{l-m}(\hat{\mathbf{r}})]. \quad (97)$$

$$Y_{l-m}(\hat{\mathbf{r}}) \equiv \frac{1}{\sqrt{2}} [y_{lm}(\hat{\mathbf{r}}) - iy_{l-m}(\hat{\mathbf{r}})]. \quad (98)$$

.

---

The definition of  $Y_{lm}(\hat{\mathbf{r}})$  are

$$Y_{lm}(\theta, \phi) = (-1)^m \left[ \frac{(2l+1)(l-m)!}{4\pi(l+m)!} \right]^{\frac{1}{2}} P_l^m(\cos(\theta)) e^{im\phi}, \quad (99)$$

$$P_l^m(x) = \frac{(1-x^2)^{m/2}}{2^l l!} \frac{d^{l+m}}{dx^{l+m}} (x^2 - 1)^l \quad (100)$$

.

We take these definitions from

(1)A.R.Edmonds, Angular Momentum in quantum Mechanics, Princeton University Press, 1960,

(2)M.E.Rose, Elementary Theory of angular Momentum, John Wiley & Sons, INC. 1957, if necessary. The definition of spherical hermonics are the same in these books.

## E Notations (Usuda's old note from here) Need fixing.

...xxxxx under construction xxxxx...

In this note, we denote the primitive lattice vector as  $\{\mathbf{a}_i|i=1,2,3\}$  (`=alat*plat(1:3,i)`), the volume of unit cell as  $\Omega = |\mathbf{a}_1 \times \mathbf{a}_2 \cdot \mathbf{a}_3|$ , and the reciprocal lattice vector as  $\{\mathbf{b}_i|i=1,2,3\}$  (`=2*pi*qplat(1:3,i)/alat`).

We assume the periodic boundary condition for quantities as  $\Psi(\mathbf{r}) = \Psi(\mathbf{r} + N_1\mathbf{a}_1) = \Psi(\mathbf{r} + N_2\mathbf{a}_2) = \Psi(\mathbf{r} + N_3\mathbf{a}_3)$ . Correspondingly, we use a Brillouin zone (BZ) discrete mesh, which is given as

$$\mathbf{k}(i_1, i_2, i_3) = 2\pi \left( \frac{i_1}{N_1} \mathbf{b}_1 + \frac{i_2}{N_2} \mathbf{b}_2 + \frac{i_3}{N_3} \mathbf{b}_3 \right) \quad (101)$$

for  $i_1 = 0, 1, 2, \dots, N_1 - 1$  and so on. Within the volume  $V = \Omega N_c = \Omega N_1 N_2 N_3$ , we normalize eigenfunctions and so on. However, it is rather convenient to use the normalization within a unit cell  $\Omega$  because we know the property

$$\int_V F^{\mathbf{k}}(\mathbf{r}) G^{\mathbf{k}'}(\mathbf{r}) d^3r = \delta_{\mathbf{k}\mathbf{k}'} N_c \int_{\Omega} F^{\mathbf{k}}(\mathbf{r}) G^{\mathbf{k}'}(\mathbf{r}) d^3r \quad (102)$$

for any functions  $F^{\mathbf{k}}$  and  $G^{\mathbf{k}'}$  with the Bloch periodicity specified by  $\mathbf{k}$  and  $\mathbf{k}'$ . In the GW code, we store the cell-normalized eigenfunction  $\tilde{\Psi}^{\mathbf{k}n}(\mathbf{r})$  to DATA4GW;

$$\tilde{\Psi}^{\mathbf{k}n}(\mathbf{r}) \equiv \sqrt{N_c} \Psi^{\mathbf{k}n}(\mathbf{r}) \quad (103)$$

$$\int_{\Omega} |\tilde{\Psi}^{\mathbf{k}n}(\mathbf{r})|^2 d^3r = 1. \quad (104)$$

This  $\tilde{\Psi}^{\mathbf{k}n}(\mathbf{r})$  is expanded as

$$\tilde{\Psi}^{\mathbf{k}n}(\mathbf{r}) = \sum_{au} \alpha_{au}^{\mathbf{k}n} A_{au}^{\mathbf{k}}(\mathbf{r}) + \sum_{\mathbf{G}} \beta_{\mathbf{G}}^{\mathbf{k}n} P_{\mathbf{G}}^{\mathbf{k}}(\mathbf{r}), \quad (105)$$

$$A_{au}^{\mathbf{k}}(\mathbf{r}) \equiv \sum_{\mathbf{T}} A_{au}(\mathbf{r} - \mathbf{R}_a - \mathbf{T}) e^{i\mathbf{k} \cdot \mathbf{T}}, \quad (106)$$

$$\begin{aligned} P_{\mathbf{G}}^{\mathbf{k}}(\mathbf{r}) &\equiv 0 \quad \text{if } \mathbf{r} \in \text{any MT} \\ &\equiv e^{i(\mathbf{k} + \mathbf{G}) \cdot \mathbf{r}} \quad \text{otherwise,} \end{aligned} \quad (107)$$

where  $A_{au}^{\mathbf{k}}(\mathbf{r})$  is the Bloch sum of the atomic function  $A_{au}(\mathbf{r})$  in the  $a$ -site muffin-tin (MT) sphere.  $P_{\mathbf{G}}^{\mathbf{k}}(\mathbf{r})$  denotes the interstitial plane wave (IPW). Here  $\mathbf{T}$  is the lattice translation vector;  $\mathbf{R}_a$  is the position of the  $a$ -site in the cell;  $\mathbf{G}$  denotes the reciprocal vector;  $u$  denotes the index to specify the argumentaion basis.  $A_{au}^{\mathbf{k}}(\mathbf{r})$  is orthnornalized as

$$\int_{|\mathbf{r}| < V_a} A_{au}(\mathbf{r}) A_{au'}(\mathbf{r}) d^3r = \delta_{uu'}, \quad (108)$$

where  $V_a$  is the size of the  $a$ -site MT. The normalization is

$$\frac{1}{N_c} \int_V \{A_{au}^{\mathbf{k}}(\mathbf{r})\}^* A_{a'u'}^{\mathbf{k}'}(\mathbf{r}) d^3r = \delta_{\mathbf{k}\mathbf{k}'} \delta_{aa'} \delta_{uu'} \int_{\Omega} |A_{au}^{\mathbf{k}}(\mathbf{r})|^2 d^3r = \delta_{\mathbf{k}\mathbf{k}'} \delta_{aa'} \delta_{uu'} \quad (109)$$

$$\frac{1}{N_c} \int_V \{P_{\mathbf{G}}^{\mathbf{k}}(\mathbf{r})\}^* P_{\mathbf{G}'}^{\mathbf{k}'}(\mathbf{r}) d^3r = \delta_{\mathbf{k}\mathbf{k}'} \int_{\Omega} \{P_{\mathbf{G}}^{\mathbf{k}}(\mathbf{r})\}^* P_{\mathbf{G}'}^{\mathbf{k}'}(\mathbf{r}) d^3r = \delta_{\mathbf{k}\mathbf{k}'} \int_{\Omega} P_{\mathbf{G}' - \mathbf{G}}^0(\mathbf{r}) d^3r \quad (110)$$

## F Expansion of non-local functions, need fixing

...xxxxx under construction xxxxx...

We expand the Coulomb interaction  $v(\mathbf{r}, \mathbf{r}') = e^2/|\mathbf{r} - \mathbf{r}'|$  as

$$\begin{aligned} v(\mathbf{r}, \mathbf{r}') &= \frac{1}{N_c} \sum_{\mathbf{k}} \sum_{IJ} \tilde{M}_I^{\mathbf{k}}(\mathbf{r}) v_{IJ}(\mathbf{k}) \{\tilde{M}_J^{\mathbf{k}}(\mathbf{r}')\}^* \\ v_{IJ}(\mathbf{k}) &= \frac{1}{N_c} \int_V d^3r \int_V d^3r' \{M_I^{\mathbf{k}}(\mathbf{r})\}^* v(\mathbf{r}, \mathbf{r}') M_J^{\mathbf{k}}(\mathbf{r}') \end{aligned} \quad (111)$$

This expansion is general for the two-point non-local functions. However, for convenience, we expand the polarization function  $D$  as

$$\begin{aligned} D(\mathbf{r}, \mathbf{r}', \omega) &= \frac{1}{N_c} \sum_{\mathbf{k}} \sum_{IJ} M_I^{\mathbf{k}}(\mathbf{r}) D_{IJ}(\mathbf{k}, \omega) \{M_J^{\mathbf{k}}(\mathbf{r}')\}^* \\ D_{IJ}(\mathbf{k}, \omega) &= \frac{1}{N_c} \int_V d^3r \int_V d^3r' \{\tilde{M}_I^{\mathbf{k}}(\mathbf{r})\}^* D(\mathbf{r}, \mathbf{r}', \omega) \tilde{M}_J^{\mathbf{k}}(\mathbf{r}') \end{aligned} \quad (112)$$

and the dielectric function  $\epsilon$  (and also the inverse dielectric function  $\epsilon^{-1}$ ) as

$$\begin{cases} \epsilon(\mathbf{r}, \mathbf{r}', \omega) = \frac{1}{N_c} \sum_{\mathbf{k}} \sum_{IJ} \tilde{M}_I^{\mathbf{k}}(\mathbf{r}) \epsilon_{IJ}(\mathbf{k}, \omega) \{M_J^{\mathbf{k}}(\mathbf{r}')\}^* \\ \epsilon_{IJ}(\mathbf{k}, \omega) = \frac{1}{N_c} \int_V d^3r \int_V d^3r' \{M_I^{\mathbf{k}}(\mathbf{r})\}^* \epsilon(\mathbf{r}, \mathbf{r}', \omega) \tilde{M}_J^{\mathbf{k}}(\mathbf{r}'). \end{cases} \quad (113)$$

## G Expansion of a plane wave with the mixed basis, need fixing

...xxxxx under construction xxxxxx...

If we substitute a plane wave  $e^{i\mathbf{k}\cdot\mathbf{r}}/\sqrt{\Omega}$  for  $F^{\mathbf{k}}(\mathbf{r})$  in Eq.(32), we have

$$\begin{cases} \frac{1}{\sqrt{\Omega}} e^{i\mathbf{k}\cdot\mathbf{r}} = \sum_J M_J^{\mathbf{k}}(\mathbf{r}) \tilde{C}_J^{\mathbf{k}0} \\ \tilde{C}_J^{\mathbf{k}0} = \frac{1}{\sqrt{\Omega}} \int_{\Omega} \{\tilde{M}_J^{\mathbf{k}}(\mathbf{r})\}^* e^{i\mathbf{k}\cdot\mathbf{r}} d^3r. \end{cases} \quad (114)$$

For small  $\mathbf{k}$ , the maximum eigenvalue of the Coulomb matrix should be  $v(\mathbf{k}) \equiv 4\pi e^2/|\mathbf{k}|^2$  and the corresponding eigenvector should be equal to  $\tilde{C}_J^{\mathbf{k}0}$ . So we can get  $\tilde{C}_J^{\mathbf{k}0}$  from the eigenvalue problem instead of evaluating the integral of Eq.(114).

In `hvvccfp0.m.f`, we get the maximum eigenvalue  $\epsilon^0(\mathbf{k})$  and corresponding eigenvector  $\tilde{C}_J^{\mathbf{k}0}$  from

$$\sum_J [v_{IJ}(\mathbf{k}) - \epsilon^0(\mathbf{k}) O_{IJ}^{\mathbf{k}}] \tilde{C}_J^{\mathbf{k}0} = 0. \quad (115)$$

Then we check the normalization

$$\sum_{IJ} (\tilde{C}_I^{\mathbf{k}0})^* O_{IJ}^{\mathbf{k}} \tilde{C}_J^{\mathbf{k}0} = 1 \quad (116)$$

and calculate the two quantities

$$v(\text{exact}) = \Omega \frac{4\pi e^2}{|\mathbf{k}|^2}, \quad (117)$$

$$v(\text{cal}) = \Omega \sum_{IJ} (\tilde{C}_I^{\mathbf{k}0})^* v_{IJ}(\mathbf{k}) \tilde{C}_J^{\mathbf{k}0} = \Omega \epsilon^0(\mathbf{k}), \quad (118)$$

which are shown in the end of the output of `hvvccfp0.m.f` (`lvcc` by the script `gw_lmf` or `eps_lmf`) such as follows.

```
--- vcoul(exact)= 0.166657D+05 absq2= 0.5565111898526868D-01
--- vcoul(cal ) = 0.166587D+05 -0.484112D-19
```

You can see the agreement is good enough! The quantity  $\tilde{C}_J^{\mathbf{k}0}$  is stored into `Mix0vec`. It is read into the variable `gbvec` in `hx0fp0.m.f`. We also store the next quantity;

$$\begin{aligned} C_J^{\mathbf{k}0} &\equiv \frac{1}{\sqrt{\Omega}} \int_{\Omega} \{M_J^{\mathbf{k}}(\mathbf{r})\}^* e^{i\mathbf{k}\cdot\mathbf{r}} d^3r \\ &= \sum_I \{O_{IJ}\}^* \frac{1}{\sqrt{\Omega}} \int_{\Omega} \{\tilde{M}_I^{\mathbf{k}}(\mathbf{r})\}^* e^{i\mathbf{k}\cdot\mathbf{r}} d^3r \\ &= \sum_I O_{JI} \tilde{C}_I^{\mathbf{k}0}. \end{aligned} \quad (119)$$

It is read into the variable `zzr` in `hx0fp0.m.f`.

## H Dielectric function xxxxxxxxx

...xxxxx under construction xxxxx...

### H.1 Dielectric function without local-field correction

...xxxxx under construction xxxxx...

Approximating  $\epsilon^{-1}(\mathbf{q}, \omega)$  as  $1/\epsilon(\mathbf{q}, \omega)$  corresponds to neglecting the local-field correction.  $\epsilon(\mathbf{q}, \omega)$  is given as

$$\begin{aligned}\epsilon(\mathbf{q}, \omega) &= \frac{1}{V} \int_V d^3r \int_V d^3r' e^{-i\mathbf{q}\cdot\mathbf{r}} \epsilon(\mathbf{r}, \mathbf{r}', \omega) e^{i\mathbf{q}\cdot\mathbf{r}'} \\ &= 1 - \frac{1}{V} \int_V d^3r \int_V d^3r' \int_V d^3r'' e^{-i\mathbf{q}\cdot\mathbf{r}} e^{i\mathbf{q}\cdot\mathbf{r}'} v(\mathbf{r}, \mathbf{r}'') D(\mathbf{r}'', \mathbf{r}', \omega) \\ &= 1 - v(\mathbf{q}) D(\mathbf{q}, \omega),\end{aligned}\tag{120}$$

where the relation

$$\int_V v(\mathbf{r}, \mathbf{r}'') e^{-i\mathbf{q}\cdot\mathbf{r}} d^3r = v(\mathbf{q}) e^{-i\mathbf{q}\cdot\mathbf{r}''}\tag{121}$$

is used and

$$v(\mathbf{q}) = \sum_{IJ} (\tilde{C}_I^{\mathbf{q}0})^* v_{IJ}(\mathbf{q}) \tilde{C}_J^{\mathbf{q}0},\tag{122}$$

$$D(\mathbf{q}, \omega) = \sum_{IJ} (C_I^{\mathbf{q}0})^* D_{IJ}(\mathbf{q}, \omega) C_J^{\mathbf{q}0}.\tag{123}$$

In `hx0fp0.m.f`, we calculate  $v(\mathbf{q})$ ,  $D(\mathbf{q}, \omega)$  and  $\epsilon(\mathbf{q}, \omega)$  by

```
vcmean = sum( dconjg(gbvec) * matmul(vcoul,gbvec) )
x0mean = sum( dconjg(zzr) * matmul(zxq(:, :, iw), zzr) )
eps(iw, iqixc2) = 1- vcmean * x0mean
```

and the inverse dielectric function is given by  $1/\text{eps}(iw, iqixc2)$ . The matrix element of the polarization,  $D_{IJ}(\mathbf{q}, \omega) = \mathbf{zxq}$ , is obtained from the subroutine `x0kf`. The results of  $\text{Re}(\epsilon)$ ,  $\text{Im}(\epsilon)$ ,  $\text{Re}(\epsilon^{-1})$  and  $\text{Im}(\epsilon^{-1})$  are stored in `EPS01.nolfc.dat`.

### H.2 Dielectric function with local-field correction

...xxxxx under construction xxxxx...

The inverse dielectric function  $\epsilon^{-1}(\mathbf{q}, \omega)$  is calculated as follows:

$$\begin{aligned}\epsilon^{-1}(\mathbf{q}, \omega) &= \frac{1}{V} \int_V d^3r \int_V d^3r' e^{-i\mathbf{q}\cdot\mathbf{r}} \epsilon^{-1}(\mathbf{r}, \mathbf{r}', \omega) e^{i\mathbf{q}\cdot\mathbf{r}'} \\ &= \sum_{IJ} \left\{ \frac{1}{\sqrt{\Omega}} \int_{\Omega} \tilde{M}_I^{\mathbf{q}}(\mathbf{r}) e^{-i\mathbf{q}\cdot\mathbf{r}} d^3r \right\} \epsilon_{IJ}^{-1}(\mathbf{q}, \omega) \left\{ \frac{1}{\sqrt{\Omega}} \int_{\Omega} \{M_J^{\mathbf{q}}(\mathbf{r}')\}^* e^{i\mathbf{q}\cdot\mathbf{r}'} d^3r' \right\} \\ &= \sum_{IJ} (\tilde{C}_I^{\mathbf{q}0})^* \epsilon_{IJ}^{-1}(\mathbf{q}, \omega) C_J^{\mathbf{q}0}.\end{aligned}\tag{124}$$

In `hx0fp0.m.f`, we calculate  $\epsilon^{-1}(\mathbf{q}, \omega)$  by

```
epsi(iw, iqixc2) = sum( dconjg(gbvec) * matmul(zw0, zzr) )
```

and the dielectric function is given by  $1/\text{epsi}(iw, iqixc2)$ . The matrix element of  $\epsilon_{IJ}^{-1}(\mathbf{q}, \omega) = \mathbf{zw0}$  is obtained from the subroutine `wcf`. The results of  $\text{Re}(\epsilon)$ ,  $\text{Im}(\epsilon)$ ,  $\text{Re}(\epsilon^{-1})$  and  $\text{Im}(\epsilon^{-1})$  are stored in `EPS01.dat`.

## I TODO list(will be written)

ESEAVR (average of  $\sigma$  at high energy)

Rotation of  $q$  by space group (not unique if  $q$  is on the BZ boundary).  
Discontinuity of bands at BZ boundary

Mechanism of GW calculation for Metal. Drude weight.

Tetrahedron method. Accumulation of imaginary part, and Hilbert transformation. No time-reversal sym
